\* June to December.

NOTE to analyses of 1895: Odor, generally distinctly vegetable, occasionally mouldy or unpleasant.

— The samples were collected from the brook, about 50 feet below the first road above Reservoir No. 3, at a depth of 1 foot beneath the surface.

*Microscopical Examination.*

The average number of organisms per cubic centimeter found in these samples was 203.

BOSTON.

\* June to December.

**NOTE to analyses of 1895:** Odor, vegetable and occasionally unpleasant, becoming somewhat stronger on boiling. — The samples were collected from the reservoir, near the gate-house, at a depth of 8 feet beneath the surface. For monthly record of height of water in this reservoir, see table at end of Boston analyses.

\* June to December.

NOTE to analyses of 1895: Odor, generally vegetable, sometimes none, becoming stronger and somewhat unpleasant on heating. — The samples were collected in the gate-house. For monthly record of  $\delta$  of water in this lake, see table at end of Boston analyses.

Where more than one sample was collected in a month the mean analysis for that month has been in making the average.  
June to December.

NOTE to analyses of 1895: Odor, generally unpleasant or disagreeable; in February and March, etc. The odor was generally stronger on heating.—The samples were collected from the near the gate-house. For monthly record of height of water in this lake, see table at end of Boston rec.

**WATER SUPPLY OF BRADFORD.**

On the advice of the State Board of Health to the Bradford Water Company, relative to the introduction of a new supply from Johnson's Pond in Boxford and Groveland and as to the improvement of the existing supply, is given on pages 15 and 16 of this volume. Analyses of samples of water from Johnson's Pond may be found on page 164 of the annual report for 1894.

The works of the Bradford Water Company were taken by the State of Bradford on April 1, 1895, and works for the introduction of a new supply from Johnson's Pond were partially constructed at the end of 1895, but as yet no water has been supplied to the town from this source.

## BRAINTREE.

## WATER SUPPLY OF BRAINTREE.

1 August, September and October the water from the Braintree r-gallery was affected by the presence of an excessive amount of iron, as will be seen by reference to the analyses in the table below.

Iron oxidizes on exposure to the air and precipitates, causing a milky turbidity and then a rusty precipitate. Information as to the effect of the presence of iron in ground waters may be found in the explanatory note on page 75.

*Chemical Examination of Water from the Filler-gallery of the Braintree Water Works.*

\* June, 1887, to May, 1888.

As to analyses of 1895: Odor, in January and July, distinctly vegetable; in February and October, earthy; in November, faintly sweetish; at other times, none. In January and November the odor appeared on heating. — The samples were collected from a faucet at the pumping station.

**WATER SUPPLY OF BRIDGEWATER AND EAST BRIDGEWATER. —  
BRIDGEWATERS WATER COMPANY.**

During the year 1895 nine tubular wells, each 6 inches in diameter, were added to the works. These wells are located about 1,000 feet east of the pumping station, in a line at right angles to the course of the river, and are about 200 feet apart in the line. They are from 90 to 165 feet in depth and are sunk in rock, the surface of which is from 30 to 50 feet beneath the surface of the ground. An analysis of a sample of water from one of the wells, which is 160 feet deep, is given on the following page.

*Chemical Examination of Water from the Wells of the Bridgewaters Water Company.*

\* June to December.

As to analyses of 1895: Odor, vegetable, frequently becoming somewhat stronger on heating. —  
 pies were collected from the reservoir near the gate-house, 1 foot beneath the surface. For  
 record of height of water in this reservoir, see page 125.

## BROCKTON.

| 14384   | May 29              | Distinct.   | Cons.     | .68    | 3.40                    | 1.90              | .0020    | .0226       | .0204      | .0022      | .16       | .0000       | .0000     | .6574            | 0.9       |

Odor of the first sample, vegetable; of the second, none, becoming distinctly vegetable on heating.

— The samples were collected from Rice's mill-pond, about one mile south of Brookfield village, on the stream which joins the Quabog River near the Brookfield station of the Boston & Albany Railroad.

*Microscopical Examination.*

The total number of organisms per cubic centimeter found in each of these samples was as follows: No. 14012, 159; No. 14384, 228.

**WATER SUPPLY OF BROOKLINE.***Chemical Examination of Water from a Faucet at the Low-service Pumping Station of the Brookline Water Works.*

\* June to December.

NOTE to analyses of 1895: Odor, vegetable, frequently becoming stronger and sometimes unpleasant on heating. — The samples were collected from the pump well at the pumping station. For monthly record of height of water in this pond, see page 135.

Hor. faintly unpleasant, becoming distinctly vegetable on heating. — The sample was collected the reservoir at a time when the water was unusually low.

*Microscopical Examination.*

Is insignificant number of organisms was found in this sample.

## CHESTER.

## WATER SUPPLY OF CHESTER.

*Chemical Examination of Water from the Austin Brook Reservoir of  
Chester Water Works.*

NOTE to analyses of 1895: Odor, vegetable or none; in May, vegetable and unpleasant. — 1 was collected from a brook flowing into Cooley Brook reservoir from the northwest; the other from Cooley Brook Reservoir.

*Microscopical Examination.*

The average number of organisms per cubic centimeter found in these samples was 67. The number was found in May, and consisted chiefly of *Zoëglia*.

## CHICOPEE.

No organisms.

## DIGHTON AND SOMERSET.

The advice of the State Board of Health to James H. Flint and others (petitioners for incorporation as the Dighton and Somerset Water Company, relative to taking the waters of Muddy Brook and Segreganset River and their tributaries in the town of Dighton, and water from any wells in these towns) may be found on pages 18-20 of this volume. Analyses of samples from various sources investigated are given below.

DIGHTON AND SOMERSET.

*Chemical Examination of Water from Muddy Cove Brook, Dighton.*

[Parts per 100,000.]

odor, vegetable. — The first sample was collected from a faucet in the city, the second from a faucet at the pumping station, and the last from the gate-house at the lake.

## Microscopical Examination.

The total number of organisms per cubic centimeter found in each of these samples was as follows: No. 3579, 609; No. 14202, 229; No. 14346, 228.

## FITCHBURG.

## WATER SUPPLY OF FITCHBURG.

\* June to December.

NOTE to analyses of 1895: Odor, vegetable, and occasionally also unpleasant or mouldy. — The samples were collected from the reservoir. The heights of water in this reservoir on dates when samples of water were collected for analysis were as follows: February 19, 25 feet; May 16, 38 feet; August 20, 21 feet; November 19, 25 feet.

Where more than one sample was collected in a month the mean analysis for that month has been in making the average.

October.

forms to analyses of 1895: Odor, frequently faintly earthy or musty, often none; on heating, times unpleasant or disagreeable. — The samples were collected from the underdrain at its outlet, the exception of No. 15516, which was collected from a manhole.

The analysis of 1889 was made before sewage was admitted to the sewers. Several of the analyses in 1890 and those of the years 1891 to 1894 inclusive were made by the city of Boston.

\* June to December.

† January to May.

‡ June, three samples.

§ March.

NOTE to analyses of 1895: Odor of the first and last samples, none, becoming distinctly vegetable on heating; of the second sample, distinctly vegetable, disappearing on heating. — The first and second samples were collected from faucets in the town and the last from Crystal Lake.

*Microscopical Examination.*

The total number of organisms per cubic centimeter found in each of these samples was as follows: No. 13691, 36; No. 14682, 293; No. 15406, 32. The number of *Cyanophyceae* was as follows: No. 13691, 0; No. 14682, 76; No. 15406, 4.

## GLOUCESTER.

## WATER SUPPLY OF GLOUCESTER.

The works of the Gloucester Water Company were taken by the city Oct. 1, 1895.

The advice of the State Board of Health to the city of Gloucester, relative to its present and prospective sources of water supply, may be found on pages 20-23 of this volume. Analyses of samples of water collected during the investigation of the present supply and of the proposed sources of supply are given in the following tables.

*Chemical Examination of Water from Duke's Brook Storage Reservoir, Gloucester.*

Odor of Nos. 13756, 13757, 13759 and 13761 faintly vegetable; of Nos. 13758 and 13760 distinctly vegetable. On heating, the odor of Nos. 13756, 13757 and 13759 was distinctly vegetable and unpleasant and of No. 13758 very disagreeable. — No. 13756 was collected from Haskell's Brook just above the dam of Haskell's Reservoir; No. 13757, from Fernwood Lake at Homan's ice-house; No. 13758, from Lily Pond Brook near the pumping station of the Gloucester Water Company; No. 13759, from Norman's Wee Brook in Magnolia Swamp, about  $\frac{1}{2}$  mile below Western Avenue; No. 13760, from a brook in Cedar Swamp near Bennett's Hill; No. 13761, from a brook in Cedar Swamp near Magnolia Avenue.

*Microscopical Examination.*

The total number of organisms per cubic centimeter found in each of these samples was as follows: No. 13756, 1; No. 13757, 236; No. 13758, 363; No. 13759, 14; No. 13760, 4; No. 13761, 1.

## WATER SUPPLY OF GRAFTON. — GRAFTON WATER COMPANY.

*Chemical Examination of Water from the Filler-gallery of the Grafton Water Company.*

Odor, none. — The first sample was collected from a faucet at the office of the water company, and the second from the pump well at the pumping station.

*Microscopical Examination.*

No. 14733. Cyanophyceæ, *Oscillaria*, 2. Infusoria, *Peridinium*, 23. Total, 30.

No. 14951. Diatomaceæ, *Synedra*, 4. Algeæ, *Scenedesmus*, 1. Infusoria, *Peridinium*, 5. Total, 10.

## GREENFIELD.

## WATER SUPPLY OF GREENFIELD.

In the early part of 1895 a pumping station was erected on the bank of Green River, in order to obtain an auxiliary supply from the river, but no water was drawn from this source for the supply of the town during the year.

The advice of the State Board of Health to the town of Greenfield, with reference to the use of Green River as a source of additional water supply for the town, may be found on pages 23 and 24 of this volume. Analyses of samples of water from this source may be found on page 382 of the annual report for 1894.

## GROTON.

The advice of the State Board of Health to the town of Groton relative to a public water supply for the town may be found on pages 24 and 25 of this volume. Analyses of samples of water collected from various sources in the town, in connection with the investigations of the Board, are given in the following tables.

*Chemical Examination of Water from Badducok Pond, Groton.*

| 1895.   |                     |             |           |        |                         |                   |          |             |            |            |           |             |           |                  |           |
| 13935   | Mar. 2              | Decided.    | Cons.     | .75    | 9.65                    | 2.65              | .1440    | .0472       | .0368      | .0104      | .25       | .0030       | .0000     | .9971            | 4.6       |
| 14350   | May 22              | Distinct.   | Cons.     | .40    | 4.85                    | 1.70              | .0014    | .0164       | .0154      | .0010      | .40       | .0170       | .0003     | .4028            | 1.6       |

Odor of the first sample, decidedly disagreeable; of the second, distinctly vegetable. — The first sample was collected from the pond; the last, from a tap supplied with water pumped from the Nashua River.

*Microscopical Examination.*

The total number of organisms per cubic centimeter found in each of these samples was as follows: No. 13935, 171; No. 14350, 326.

*Chemical Examination of Water from Cady Pond and a Spring near its Westerly Shore.*

Odor, none. — The sample was collected from a faucet in the school.

*Microscopical Examination.*

Fungi, *Crenothrix*, 572.

## HATFIELD.

The advice of the State Board of Health to the town of Hatfield, with reference to taking a water supply from Running Gutter Brook in the westerly part of the town, may be found on pages 25 and 26 of this volume. The results of an analysis of a sample of water from this brook are given on the following page.

**HATFIELD.***Chemical Examination of Water from Running Gutter Brook, Hatfield.*

[Parts per 100,000.]

| Number. | Date of Collection. | APPEARANCE. |                |        | RESIDUE ON EVAPORATION. |                   | AMMONIA. |             |            |            | Chlorine. | NITROGEN AS |           | Oxygen Consumed. | Hardness. |

|         |                     |             |                |        |                         |                   |          | Total.      | Dissolved. | Suspended. |           |             |           |                  |           |
| 13826   | 1895.<br>Feb. 15    | None.       | Cons., earthy. | .08    | 3.95                    | 0.85              | .0000    | .0026       | .0012      | .0014      | .10       | .0120       | .0000     | .1000            | 1.8       |

Odor, faintly vegetable. — The sample was collected from the brook at the first road crossing above its junction with Broad Brook, and a short distance below the site of a proposed reservoir.

*Microscopical Examination.*

Diatomaceæ, Cocconeis, 1. Algae, Protococcus, 1. Total, 2.

**WATER SUPPLY OF HAVERHILL.**

In 1895 an additional supply of water was introduced into the city of Haverhill from East Meadow River in the north-easterly part of the city, and a storage reservoir was constructed upon the stream at Millvale, about half a mile from the point where it enters the Merrimack River.

The reservoir has an area of about 50 acres and a capacity of about 125,000,000 gallons. Its maximum depth at high water is 15 feet and its average depth 7 feet. It was thoroughly prepared for the storage of water by removing the soil, mud and vegetable matter from the area to be flowed.

The water from this source is pumped into the easterly end of Kenoza Lake through a 24-inch main about one mile in length, the surface of Kenoza Lake at high water being 18 feet above the high-water level of the Millvale Reservoir.

The watershed of East Meadow River tributary to the Millvale Reservoir has an area of 7.75 square miles, on which there is a very small population. There is one small pond on the watershed about 3 miles above the reservoir, and there is a considerable area of swamp in the vicinity of the river, a large portion being located within a short distance of the reservoir.

## HAVERHILL.

*Chemical Examination of Water from Crystal Lake, Haverhill.*

[Parts per 100,000.]

Odor of the first sample, very faintly vegetable; of the second, decidedly vegetable. — The first sample was collected from the river just above the point where it crosses Millville Road, about half a mile from its mouth. The second sample was collected from the river at Thompson's bridge, just above the reservoir.

*Microscopical Examination.*

The total number of organisms per cubic centimeter found in each of these samples was as follows : in April, 1; in July, 44.

## WATER SUPPLY OF HINGHAM AND HULL. — HINGHAM WATER COMPANY.

*Chemical Examination of Water from Accord Pond, Hingham.*

\* Milky at first; a few hours later, 0.25.

† This determination was made after the water had been filtered through filter-paper.

Odor, none. — The samples were collected from tubular test wells in Hingham, located as follows: No. 14758, in the valley of Weir River, just above Union Street; No. 14848, at the junction of two roads above High Street; No. 14903, beside a pond on South Pleasant Street.

*Microscopical Examination.*

No organisms.

## WATER SUPPLY OF HOLBROOK.

(See Randolph)

## HOLDEN.

The advice of the State Board of Health to the town of Holden with reference to the introduction of a water supply into that town from sources in the towns of Rutland and Holden may be found on pages 28 and 29 of this volume. The results of an analysis of a sample of water from Pine Hill reservoir in Holden are given below. Analyses of water from Muschopauge Pond in Rutland may be found under Rutland.

*Chemical Examination of Water from Pine Hill Reservoir, Holden.*

Odor of the first sample, none; of the second, faintly vegetable, becoming stronger on heating; of the third, faintly mouldy; of the last, faintly vegetable, becoming stronger and also musty on heating. — The first sample was collected from Tucker Brook,  $\frac{1}{2}$  mile above its junction with Manhan Brook; the second, from Tucker Brook, just above the junction; the third, from Manhan Brook,  $\frac{1}{2}$  mile above its junction with Tucker Brook; and the last, from Manhan Brook, just above the junction of the two brooks.

*Microscopical Examination.*

An insignificant number of organisms was found in each of these samples.

June to December.

† January to May.

‡ February and August.

June and September.

|| Two samples in July.

analyses of 1895: Odor, generally none; in August, unpleasant; in October, faintly vegetable samples were collected from a faucet at the pumping station.

Odor, generally none. — The samples were collected from a faucet in the office of the Milton Water Company.

*Microscopical Examination.*

No organisms were found in the samples collected in April, June, September and October. In the other samples small numbers of Crenothrix were found, as follows: in February, 2; in March, 1; in July, 40; in November, 2; in December, 1.

\* June to December.

† August and September.

‡ July.

NOTE to analyses of 1895: Odor, generally decidedly vegetable and musty or disagreeable, and occasionally offensive. — The samples were collected from the river, opposite the works of the Hyde Park Water Company. The river is not used directly as a source of water supply.

**HYDE PARK AND MILTON.***Microscopical Examination of Water from the Neponset River at Hyde Park.*

\* Where more than one sample was collected in a month the mean analysis for that month has been used in making the average.

Odor, generally faintly vegetable, sometimes none. The samples which had no odor when cold had vegetable odors when heated, and in the others the odors became stronger and sometimes also mouldy on eating — The samples were collected from the brook at its entrance to the storage reservoir.

*Microscopical Examination.*

The average number of organisms per cubic centimeter found in these samples was 42.

\* Where more than one sample was collected in a month the mean analysis for that month has been used in making the average.

Odor, generally vegetable, often also mouldy or unpleasant, seldom none. On heating, frequently stronger and mouldy or unpleasant. — The samples were collected from the reservoir.

When this reservoir was filled, in November, 1894, about 10,000,000 gallons of water from Bull Brook were diverted into it.

Odor, very faintly vegetable.

*Microscopical Examination.*

Fungi, *Crenothrix*, 3.

## WATER SUPPLY OF LAWRENCE.

The following tables contain analyses of the unfiltered Merrimack River water, and of the filtered water at the pumping station and at the distributing reservoir. The results of more extended chemical and biological examinations of the water before and after filtration through the sand filter may be found in a subsequent portion of this report.

## LAWRENCE.

*Chemical Examination of Water from the Merrimack River above Lawrence, opposite the Intake of the Lawrence Water Works.*

\* June to November. † January to May. ‡ August to December. § July to December.

**NOTE** to analyses of 1895: Odor, until May, decidedly musty and disagreeable; during the remainder of the year, distinctly vegetable and frequently also musty or unpleasant. — The samples are collected from the river, opposite the intake of the Lawrence water works, about 1 foot beneath surface. For a record of the quantity of water flowing in the river on dates when samples of water are collected for analysis, see page 195. For a comparison of the analyses of the river water at Lowell & Lawrence for a series of years, see "Merrimack River" in the chapter on "Examination of Rivers."

**LAWRENCE.**

*Microscopical Examination of Water from the Merrimack River above Lawrence, opposite the Intake of the Lawrence Water Works.*

[Number of organisms per cubic centimeter.]

NOTE to analyses of 1895: Odor, generally vegetable. — The samples were collected from a faucet in the check-valve just beyond the pump, and represent water from the river which has passed through the sand filter, mingled with a small amount of ground water.

*Microscopical Examination of Water from the Force Main at the Pumping Station of the Lawrence Water Works.*

Odor, generally vegetable, often none. — Nos. 14700 and 14890 were collected from the reservoir; the other samples, from a faucet at the gate-house. The samples represent water flowing out of the reservoir. The reservoir is supplied with filtered water.

Odor of No. 13951, faintly vegetable; of the other samples, none. On heating, vegetable odors were developed in the first and last samples.—The samples were collected from a faucet in the village.

*Microscopical Examination.*

The average number of organisms per cubic centimeter found in these samples was 139.

**WATER SUPPLY OF LENOX.**

During the year 1895 the capacity of the reservoir on the brook tributary to the Williams River was increased and a line of pipe constructed, by which water is delivered to the town by gravity, instead of being pumped to the distributing reservoir as was formerly done. The present capacity of the reservoir is estimated to be about 20,000,000 gallons, its area about 7 acres and its depth from 6 to 30 feet. The reservoir was prepared for the storage of water by removing the soil from the bottom and sides.

**WATER SUPPLY OF LEOMINSTER.**

The advice of the State Board of Health to the town of Leominster with reference to taking Fall Brook in that town as an additional source of water supply may be found on pages 33-35 of this volume.

## LEOMINSTER.

A small dam has been constructed on the stream flowing from Haynes Reservoir, at a point about 1,500 feet below the reservoir, a pipe has been laid from this dam to Morse Reservoir, a distance of about 1,100 feet. By means of this dam and pipe line water drawn from Haynes Reservoir can be diverted into Morse Reservoir, and during the drier portion of 1895, beginning with the 1st of July, the water drawn from Haynes Reservoir was diverted to Morse Reservoir and flowed to the distributing reservoir from that latter source. The deterioration in the quality of the water of Morse Reservoir in 1895, indicated by the table of averages by years given below, was due to the diversion into it of water from Haynes Reservoir.

\* June to December.

† February to May.

NOTE to analyses of 1895: Odor, vegetable. — The samples were collected from the reservoir, quality of the water of this reservoir was affected after the first of July by the diversion into it of water from Haynes reservoir.

\* June to December.

NOTE to analyses of 1895: Odor, in July, none; at other times, vegetable; in May, also disagreeable. In heating, the odor was frequently unpleasant. — The samples were collected from the reservoir.

## LEOMINSTER.

Odor, faintly vegetable. — The first two samples were collected, respectively, from the South and North branches of Fall Brook where they cross May Street. The last sample was collected from Fall Brook at the falls, a short distance above the first road crossing below May Street.

*Microscopical Examination.*

The total number of organisms per cubic centimeter found in each of these samples was as follows : No. 14490, 382; No. 14491, 98; No. 14492, 8.

## WATER SUPPLY OF LEXINGTON.

The works of the Lexington Water Company were purchased by the town Dec. 10, 1895.

*Chemical Examination of Water from the Vine Brook Storage Reservoir of the Lexington Water Works.*

\* Where more than one sample was collected in a month the mean analysis for that month has been used in making the average.

Odor of the first three samples, vegetable and disagreeable; of the other samples, vegetable or none, some cases becoming mouldy on heating. — No. 15448 was collected from a faucet at the pumping station while pumping; the other samples were collected from the reservoir.

**WATER SUPPLY OF LINCOLN.**

(See Concord.)

**WATER SUPPLY OF LONGMEADOW.**

Population in 1895, 620. The works were built by the town, and water was first introduced Feb. 1, 1895. The source of supply is a small brook near the center of the town, from which the water is diverted into a covered collecting well. From this well the water is forced by pumps into an open iron tank 22 feet in diameter and 30 feet high. The brook has a watershed at the point of diversion of about one-half of a square mile, and has a very small population on its watershed.

The collecting well is 30 feet square and 8½ feet deep, built of masonry and covered with a wooden roof. Distributing mains are of cast iron and service pipes of galvanized iron. At the end of the year 1895 there were about 68 connections with the mains.

LOWELL.

## WATER SUPPLY OF LOWELL.

During the year 1895 a second system of tubular wells for supplying water to the city of Lowell was constructed in the valley of River Meadow Brook just above the point where it is crossed by the Old Middlesex Canal in the town of Chelmsford, the wells being distant about a mile up the valley in a straight line from the nearest of the system of tubular wells constructed in 1892.

The new system consists of about 120 2-inch wells, averaging about 45 feet in depth. Two-thirds of the wells are located in two lines 12 feet apart, parallel to the Old Middlesex Canal and about 200 feet south-west of it. The wells are 25 feet apart in the lines. The remaining wells are located in two similar parallel lines about 12 feet apart, extending from the centre of the other lines, and approximately at right angles to them. The wells in these lines are also 25 feet apart, excepting that there is a break of about 300 feet near the middle where there are no wells, the material at that point being found to consist of peaty soil to a depth ranging from 6 to 35 feet. Pumping from this system of wells into the city mains was begun April 5, 1895.

Eighteen wells have been added to the original system of wells lower down the valley.

During the year 1895 about 66 per cent. of the water supplied to the city was drawn from the systems of tubular wells in the valley of River Meadow Brook, the remainder being drawn from the Merrimack River.

The results of analyses of samples of water from the Merrimack River and from the two systems of tubular wells in the valley of River Meadow Brook are given in the following tables.

These results show that the water of the original system of tubular wells in the valley of River Meadow Brook just above Plain Street has been somewhat harder than last year and has contained a considerably greater amount of residue on evaporation.

Analyses of samples from the new system of tubular wells in the valley of River Meadow Brook have been made once in two weeks and sometimes more frequently since pumping from these wells into the city mains was begun in April. The results of these investigations show that there has been a very great increase in the color, residue on evaporation, ammonia, hardness and iron during the year, a maximum being reached in November. The iron oxidizes on

**LOWELL.**

exposure to the air, giving the water at first a milky turbidity, and subsequently precipitating in the form of a rusty sediment.

\* June to December.

† January to May.

‡ September to December.

NOTE to analyses of 1895: Odor, generally vegetable and musty or mouldy, sometimes unpleasant or disagreeable. — The samples were collected from the river, about 1 foot beneath the surface.

For a comparison of the analyses of the river at Lowell and Lawrence for a series of years, see "Merrimack River" in the chapter on "Examination of Rivers" in a subsequent portion of this report.

LOWELL.

*Chemical Examination of Water from Tubular Wells in the Valley of River Meadow Brook, a Short Distance above Plain Street.*

**NOTE** to analyses of 1895: Odor, in September, November and December, distinct; at other times, none. — The samples were collected from a faucet at the pumping station while pumping. The wells are locally known as the "Cook" wells.

*Microscopical Examination.*

The average number of organisms per cubic centimeter found in these samples was 31, consisting chiefly of *Crenothrix*.

**LOWELL.**

*Chemical Examination of Water from Tubular Wells in the Valley of River Meadow Brook, a Short Distance above the Old Middlesex Canal in Chelmsford.*

Odor of the last four samples, vegetable; of the other samples, none. — The samples were collected from a faucet at the pumping station while pumping. The wells are locally known as the "Hydraulic Company's" wells.

*Microscopical Examination.*

The average number of organisms per cubic centimeter found in these samples was 28, consisting chiefly of *Crenothrix*.

\* June to December.

**NOTE** to analyses of 1895: Odor, generally vegetable, becoming stronger and sometimes unpleasant on heating. — The samples were collected from the pond near the gate-house, about 1 foot beneath the surface.

\* June to December.

analysis of 1895: Odor, generally vegetable, sometimes also unpleasant, rarely none. — re collected from the pond near the gate-house, 1 foot beneath the surface. A portion bring this pond during the year was pumped from the Saugus River. the quality of the water of this river see reports for 1894 and 1893.

\* January to June.

† May, June and July.

NOTE to analyses of 1895: Odor, vegetable and unpleasant. — The samples were collected from the pond near the gate-house, 1 foot beneath the surface.

*Microscopical Examination of Water from Walden Pond, Lynn.*

\* Where more than one sample was collected in a month, the mean analysis for that month has been used in making the average.

† May to December.

NOTE to analyses of 1895: Odor, generally vegetable, sometimes also disagreeable, rarely none.  
— The samples were collected from the pond.

## MALDEN, MEDFORD AND MELROSE.

*Microscopical Examination of Water from Spot Pond, Stoneham.*

\* Three samples in November and December.

† June and October.

For analyses of 1898: Odor, none. — The samples were collected from a faucet at the pumping station.

*Microscopical Examination.*

A small number of organisms, chiefly *Oreothrix* and *Zodglexa*, was found in some of these samples.

## MANCHESTER.

## WATER SUPPLY OF MANCHESTER.

The works for obtaining a supply of water for the town of Manchester were extended in 1895 by sinking five 4-inch tubular wells in the valley of Sawmill Brook near Coolidge Spring, a short distance above the large well. The wells were driven to depths ranging from 27 to 34 feet, and water is pumped from them through a 6-inch pipe into the large well near the pumping station.

Odor, none. — The sample was collected from a faucet at the pumping station.

*Microscopical Examination.*

No organisms.

## WATER SUPPLY OF MARBLEHEAD.

During the year 1895 the small collecting well which was built in 1893 near a small pond in the vicinity of the pumping station was replaced by a large well constructed in the bed of the pond. The well is 25 feet in diameter and 34 feet deep, and is sunk through about 20 feet of mud into a bed of gravel. Water from this well is used at the times when the quantity of water furnished by the original well is insufficient for the supply of the town.

\* Where more than one sample was collected in a month the mean analysis for that month has been used in making the average.

Odor of the first sample, faintly musty; of the others, none.

*Microscopical Examination.*

No organisms.

**WATER SUPPLY OF MARLBOROUGH.**

During 1895 a storage reservoir was constructed on Millham Brook near its junction with the Assabet River, and a short distance below the point from which water has been pumped during a portion of the last two years for the supply of the city. The reservoir has an area of about 66 acres, and its general depth is about 25 feet. Its total storage capacity when full is 315,000,000 gallons, but by the present arrangement the available capacity above the entrance to the pipe leading to the pumping station, which is 14 feet below high water, is about 262,000,000 gallons. The area flowed contained a meadow having an area of about 30 acres, where the mud was from 3 to 6 feet in depth. The mud was not disturbed, and the only preparation which the surface received was the burning of the grass. The bottom of the reservoir at the sides was stripped of loam and vegetable matter above a level 10 feet below high water, and the stumps were removed. The loam taken from this portion of the reservoir was used in filling the shallow places, and was covered with gravel to a depth of 6 inches, making steep slopes around the shores, so that the depth is generally not less than 6 feet at high water. The watershed, exclusive of the watershed of Lake

## MARLBOROUGH.

Williams, the present source of supply, has an area of about 3.5 square miles and contains considerable population, located chiefly at the upper end.

Water from this reservoir will be supplied to the city when required by pumping at the present pumping station on Millham Brook, near the upper end of the reservoir. By means of this pumping station water can be forced to the pumping station at Lake Williams, and either discharged into the lake or pumped again to the distributing reservoir for the supply of the city.

During the spring of 1895 46,500,000 gallons of water were pumped from Millham Brook above the storage reservoir into Lake Williams, the present source of supply. This is about a quarter of the total quantity of water consumed by the city during the year.

\* June to December.

† March and April.

o analyses of 1895: Odor of the first and last samples, faintly vegetable; of the second, being distinctly vegetable and somewhat unpleasant on heating; of the third, distinctly unappearing on heating. — The first and third samples were collected from a faucet at the station while pumping, and the other samples from the lake.

*Microscopical Examination.*

number of organisms per cubic centimeter found in each of these samples was as follows: No. 14185, 79; No. 14322, 227; No. 16424, 81.

## WATER SUPPLY OF MEDFORD.

In 1895 a new dam at Wright's Pond was completed, increasing the storage capacity to about 72,000,000 gallons. The area of the pond at high water is now 23 acres, and its average depth about 10 feet. None of the soil was removed from the area flowed. The area of the watershed, including the area of the pond, is about 191 acres, consisting chiefly of wood land, and containing a very small population. Water from Wright's Pond may be pumped to supply the high-service system, or may be supplied to the town by gravity by means of a connection with the main pipe from Spot Pond to the town, which passes near Wright's Pond.

In connection with the high-service system there is a standpipe 35 feet in diameter and 60 feet in height.

In addition to the supply obtained from Wright's Pond, water is pumped at times for the supply of the city from two tributaries of the brook flowing from Wright's Pond, known as the East Arm and the West Arm. The water from these sources and from Wright's Pond can be pumped into Spot Pond if desired.

Further information regarding the water supply of Medford from Spot Pond and analyses of the water of this pond may be found on pages 217 and 218 of this volume.

Odor, none. — No. 15276 was collected from a group of new wells; the other samples, from faucets in Melrose supplied from the tubular wells.

*Microscopical Examination.*

No. 13957. Fungi, *Oreothrix*, 7.

No. 15276. Fungi, *Molds*, 1.

No organisms were found in the other samples.

## WATER SUPPLY OF METHUEN.

\* June to December.

† January to May.

‡ April and September.

NOTE to analyses of 1895: Odor, none, except in July, when it was very faintly vegetable and unpleasant. The odor of the October sample was faintly vegetable on heating. — The samples were collected from a faucet at the pumping station while pumping.

*Microscopical Examination.*

*Crenothrix* was the only organism found in any of the samples, the largest number in any one sample being 242 in November.

**WATER SUPPLY OF MILFORD. — MILFORD WATER COMPANY.**

In 1895 a filter was constructed near the pumping station, for the filtration of that portion of the water supply which is drawn directly from the Charles River. The filter has an area of about a quarter of an acre and consists of five feet in depth of sand taken from a bank in the immediate vicinity. Before being applied to the filter the water from the river is passed through a small settling basin. During the summer of 1895 it is said that about 400,000 gallons of water were filtered daily, and that the filter was cleaned about once in six weeks when running at this rate.

**MILLBURY.****WATER SUPPLY OF MILLBURY. — MILLBURY WATER COMPANY.**

Population in 1895, 5,222. The works are owned by the Millbury Water Company, and water was first introduced Nov. 16, 1895. The source of supply is a large well located near the Millbury branch of the Boston & Albany Railroad, about half a mile north of the village.

The well is built of stone masonry, and is 20 feet in diameter and 40 feet deep. Water is pumped from the well into the mains, and to a distributing reservoir about two miles distant.

The distributing reservoir is circular in shape, 135 feet in diameter, 15 feet deep, and has a capacity of about 1,500,000 gallons. It is built of stone, lined with cement, and is covered with a wooden roof.

The advice of the State Board of Health to the Millbury Water Company, with reference to the use of water from this source as a public water supply, may be found on page 35 of the annual report for 1892.

**WATER SUPPLY OF MILLIS.**

The town of Millis purchased the works of the Millis Water Company in 1894 and took possession of them on Jan. 1, 1895.

*Chemical Examination of Water from the Aqua Rex Spring, Millis.*

Odor, none. — The sample was collected from the reservoir.

*Microscopical Examination.*

Fungi, Molds, 1.

**WATER SUPPLY OF MILTON. — MILTON WATER COMPANY.**

The water supplied by this company to the town is purchased from the Hyde Park Water Company. Analyses of the water may be found on pages 183-186.

## MONSON.

## WATER SUPPLY OF MONSON.

Population in 1895, 3,746. The works are owned by the town and were completed in the spring of 1895. The source of supply is a large well in the valley of Ingalls Brook near its junction with Conant Brook, about  $2\frac{1}{2}$  miles from the village, in the westerly part of the town. The well is 73 feet in diameter at the top and 23 feet deep, and is lined with stone laid without mortar. The surface of the ground in the vicinity of the well is over 300 feet above the level of the village, and water flows directly from the well into the distributing system, by gravity.

The advice of the State Board of Health to the town of Monson relative to the use of water from this source may be found on pages 29 and 30 of the annual report for 1894.

## MONTAGUE.

The advice of the State Board of Health to a water supply committee of the village of Miller's Falls, relative to the introduction of a public water supply for the village of Miller's Falls in the towns of Montague and Erving and the village known as Lake Pleasant in Montague, by extending the pipes of the Turner's Falls water works, may be found on page 37 of this report.

An analysis of a sample of water from Green Pond, Montague, collected in connection with this investigation, is given below.

*Chemical Examination of Water from Green Pond, Montague.*

\* June to December.

† January to June.

NOTE to analyses of 1895: Odor in January, distinctly vegetable; in February, very faintly vegetable, becoming stronger and also unpleasant on heating; in July, decidedly unpleasant; no odor was detected in the remaining samples. — The samples were collected from faucets in the village.

*Microscopical Examination.*

The average number of organisms per cubic centimeter found in these samples was 20.

\* Where more than one sample was collected in a month, the mean analysis for that month has been used in making the average.

† July to November.

‡ February to May.

§ September to November.

|| March and April.

†† August to December.

\*\* May to October.

†† June to December.

NOTE to analyses of 1895: Odor, generally faintly vegetable, sometimes stronger and also unpleasant; rarely none. — The samples were collected as follows: Nos. 13603, 13940, 14257, 14423, 14600, 14714, 15324 and 15484, from the pond; Nos. 13851, 14096 and 15219, from the distributing tank; Nos. 14778 and 14971, from the main while pumping; Nos. 14901 and 15411, from a faucet in the pumping station; No. 15676, from the pump well.

\* November.

† July and August.

‡ April and October.

NOTE to analyses of 1895: Odor, none. — The first sample was collected from a faucet at a drinking fountain and the second from a faucet at the pumping station.

## Microscopical Examination.

No. 14213. No organisms.

No. 15414. Fungi, Molds, 3.

\* June to December.

NOTE to analyses of 1895: Odor, distinctly vegetable. — The samples were collected from the conduit at its entrance to the receiving reservoir, and represent water from the storage reservoir. Water from Little Quittacas Pond was drawn into the storage reservoir from June 24 to July 2, inclusive, and from July 26 to October 7, inclusive.

## NEW BEDFORD.

\* December, two samples.

† July to September, five samples.

NOTE to analyses of 1895: Odor, vegetable; of the last sample, also mouldy. — The samples were collected from the pond.

*Microscopical Examination.*

The total number of organisms per cubic centimeter found in these samples was as follows: No. 14194, 260; No. 14985, 5; No. 15819, 60.

\*June, 1887, to May, 1888.

†The very high chlorine present in the water in 1893 was due to the use at times of water from the Mack River which contained a small amount of sea water.

As to analyses of 1895: Odor in May and October, vegetable; at other times, none. In January, February, March, April and September a vegetable odor was developed on heating. — The samples collected from a faucet at No. 2 State Street.

*Microscopical Examination.*

Insignificant number of organisms was found in these samples.

\* June to December.

† February.

NOTE to analyses of 1895: Odor, none. — The samples were collected from a faucet at the pump ing station.

Analyses for the years 1887 to 1890, inclusive, represent water drawn from an open filter-basin. In 1890 the works for collecting ground water were enlarged by the construction of a long wooden filter-gallery, reinforced by tubular wells. A portion of this gallery, 732 feet in length, replaced an equal portion of the old open filter-basin. In 1892 the remaining portion of the open filter-basin was replaced by an extension of the filter-gallery, and after December of that year the water pumped for the supply of the city was not exposed to light at any point. In 1894 the works were again enlarged by the construction of a collecting conduit 3,268 feet long and by driving 52 tubular wells which are connected with the conduit.

Odor, faintly vegetable. — The samples were collected from the reservoir about 1 foot beneath surface.

*Microscopical Examination.*

The average number of organisms found in these samples was 176.

**NORTHAMPTON.***Chemical Examination of Water from Roberts' Meadow Brook, just above the Middle Reservoir of the Northampton Water Works.*

\* June to December. † January to May. ‡ April to December. § March and July.

NOTE to analyses of 1895: Odor, none. The following odors were developed on heating: first sample, none; second, distinct, peculiar; third, faintly acid; last, distinctly earthy. — The samples were collected from a faucet in the pumping station.

## Microscopical Examination.

No. 14036. Fungi, *Crenothrix*, 14. Miscellaneous, *Zoëglæa*, 40. Total, 54.

No organisms were found in the other samples.

## WATER SUPPLY OF NORTHBOROUGH.

*Chemical Examination of Water from the Upper Reservoir of the Northborough Water Works.*

[Parts per 100,000.]

\* Unfiltered.

Odor, none, becoming distinctly vegetable on heating. — The sample was collected from a filter-well in a brook near the factory of A. H. Sweet, in the vicinity of Main Street.

*Microscopical Examination.*

Algae, *Raphidium*, 1. Fungi, *Molds*, 1. Vermes, *Rotifer*, 1. Miscellaneous, *Zoöglæa*, 72. Total, 75.

## WATER SUPPLY OF NORWOOD.

The organism *Uroglæna* reappeared in the water of Buckmaster Pond in October, 1895, and increased rapidly in numbers during the remainder of the year. The taste and odor of the water became very disagreeable, and the water continued to give serious trouble from this cause in the early part of 1896.

*Chemical Examination of Water from Brooks flowing into Buckmaster Pond, Dedham.*

\* June to December.

**NOTE** to analyses of 1896: Odor, frequently vegetable and unpleasant, sometimes none; in November and December, faintly oily, becoming stronger on heating. There was also an oily odor in the March sample on heating. — The samples were collected from the pond.

## ORANGE.

## WATER SUPPLY OF ORANGE.

During 1895 a reservoir was constructed near the pumping station of the Orange water works for the purpose of collecting the water of a spring for use in supplying the town. The reservoir is oval in shape, 130 feet long, 75 feet wide and 10 feet deep, and when filled to the level of the overflow has a capacity of 600,000 gallons. The inside slopes of the basin are paved with field stones.

The organism *Uroglena* was found in considerable numbers in samples from the distributing reservoir collected in May and October. Examinations made in the early part of 1896 showed the presence of *Uroglena* in North Pond, one of the sources of supply of the town.

NOTE to analyses of 1895: Odor, in January and March, none; in October, faintly oily; at other times vegetable, and rarely unpleasant. The odor of the October sample was stronger on heating. The odor of the sample collected in May was decidedly oily on heating. — The samples were collected from the reservoir.

PAXTON

PAXTON.

The advice of the State Board of Health to the town of Paxton relative to the use of water from Asnebumskit Pond as a public water supply may be found on page 38 of this volume. An analysis of a sample of water collected from this source in August, 1893, may be found on page 394 of the annual report for 1894.

**PEPPERELL.**

The advice of the State Board of Health to the town of Pepperell in relation to a water supply for the town may be found on pages 38-40 of this volume. In connection with the investigation, samples of water were taken from five different sources in the town and in its vicinity, the results of the analyses of which are given below.

*Chemical Examination of Water from Brooks in Pepperell and Vicinity.*

Odor of the first four samples, distinctly vegetable; of the last, none, becoming distinctly vegetable on heating. — The samples were collected as follows: No. 14273, from Gulf Brook at the road crossing just above its junction with the Nisittisett River; No. 14274, from Unquetenasset Brook, below the Worcester and Nashua Division of the Boston & Maine Railroad, just above the crossing of the road from Pepperell to Hollis, New Hampshire; No. 14275, from Sucker Brook, just above where it joins the Nisittisett River; No. 14276, from the Nisittisett River, just above Sucker Brook; No. 15405, from Kemp's millpond, on Robinson's Brook, South Pepperell.

*Microscopical Examination.*

The number of organisms per cubic centimeter found in these samples was as follows: No. 14273, 54; No. 14274, 174; No. 14275, 54; No. 14276, 297; No. 15405, 70.

## PITTSFIELD.

## WATER SUPPLY OF PITTSFIELD.

In the latter part of 1895 the city of Pittsfield constructed works for taking water for the supply of the city from Mill Brook in Washington and Lenox. A dam was constructed upon the brook, forming a small reservoir at such an elevation that the water will be supplied to the city by gravity. It is said that no water was supplied to the city from this source during 1895.

In the latter part of the year the city applied to the State Board of Health for advice with reference to increasing its water supply, and during the investigations relative to an additional water supply samples of water from several sources in the vicinity of the city were analyzed, the results of which are given in the tables which follow. Analyses of samples of water from West Pond and Roaring Brook may be found under Washington.

The advice of the State Board of Health to the Onota Water Company of Pittsfield relative to the introduction of water from May Brook for the supply of that portion of the city of Pittsfield in the vicinity of West Street may be found on pages 40 and 41 of this volume.

Odor, none. — The first two samples were collected from Smith Brook at the second road crossing above West Street, and the last sample from Lulu Brook, at the first road crossing above Onota Lake.

*Microscopical Examination.*

No. 15633 was not examined. An insignificant number of organisms was found in each of the other samples.

## PITTSFIELD.

*Chemical Examination of Water from Pontoosuc Lake, Pittsfield.*

[Parts per 100,000.]

| Number. | Date of Collection. | APPEARANCE. |           |        | RESIDUE ON EVAPORATION. |                   | AMMONIA. |             |            |            | Chlorine. | NITROGEN AS |           | Oxygen Consumed. | Hardness. |

Odor, distinctly vegetable and mouldy. — The first sample was collected near the dam; the last, near the Point of Pines.

*Microscopical Examination.*

An insignificant number of organisms was found in each of these samples.

*Chemical Examination of Water from May Brook, Pittsfield.*

[Parts per 100,000.]

Odor, faintly vegetable. The sample was collected from the river at the point where it is crossed by West Street.

## Microscopical Examination.

The number of organisms per cubic centimeter found in this sample was 182.

**WATER SUPPLY OF READING.**

The advice of the State Board of Health relative to the purification of the public water supply of the town may be found on pages 41–45 of this volume. The results of analyses made during the investigation may be found on pages 297–300 of the annual report for 1894.

NOTE to analyses of 1895: Odor, vegetable or none. On heating, the odor became unpleasant in several of the samples. — The samples were collected from a faucet at the pumping station.

## REVERE AND WINTHROP.

## WATER SUPPLY OF REVERE AND WINTHROP. — REVERE WATER COMPANY.

The works of the Revere Water Company for obtaining a supply of ground water at Cliftondale, Saugus, were enlarged in 1895 by sinking fifteen additional 2½-inch tubular wells in the immediate vicinity of those driven in previous years, forming an extension of the original system. The total number now connected with these works is 67.

The rapid increase in the amount of chlorine, residue on evaporation and hardness in the water of the wells located at Revere, which has been mentioned in previous reports, still continues, as may be seen in the table of yearly averages of analyses given below. It will be noticed in the table of monthly analyses in 1895 that the water deteriorated rapidly during the months when there was the greatest draft upon the wells, owing to the infiltration of sea water.

\* June to December.

† January to May.

‡ March.

NOTE to analyses of 1895: Odor, none. — The samples were collected from a faucet at the pumping station.

*Microscopical Examination.*

Crenothrix was found in the samples collected in January, March, April, November and December, the largest number per cubic centimeter being 576, in January.

## REVERE AND WINTHROP.

*Chemical Examination of Water from Tubular Wells of the Revere Water Company, at Cliftondale, Saugus.*

\* September.

NOTE to analyses of 1895: Odor, none — The samples were collected from faucets in Revere and Saugus supplied wholly from the Saugus wells.

## Microscopical Examination.

No. 13791. Fungi, *Crenothrix*, 4.

No. 14098. Fungi, *Crenothrix*, 2.

No organisms were found in the other samples.

## BEVERE AND WINTHROP.

*Chemical Examination of Water from Brooks in Saugus.*

Odor of the first two samples, distinctly vegetable and mouldy; of the last two faintly, vegetable. — The first sample was collected from Crystal Brook, near the corner of Howard and Main streets; the second sample, from a tributary of Crystal Brook, near the corner of Howard and Main streets; the third sample, from Long Pond Brook, at the point where it crosses the Newburyport turnpike; the last sample, from a brook at the corner of Essex and Vine streets, above the point where it joins Long Pond Brook.

*Microscopical Examination.*

The total number of organisms per cubic centimeter found in these samples was as follows: No. 15598, 4; No. 15599, 155; No. 15600, 120; No. 15601, 283.

## WATER SUPPLY OF ROCKLAND.

(See *Abington.*)

## WATER SUPPLY OF ROCKPORT.

Population in 1895, 5289. The works are owned by the town and were completed in the early part of 1895. The source of supply is Cape Pond, situated in the southern part of the town. The area of the pond is 40 acres and its maximum depth is said to be about 26 feet. The pond has a watershed, including the area of the pond, of 214 acres, which contains a very small population. Water is pumped from the pond to the town and to an open iron tank, 30 feet in diameter and 60 feet in height and having a capacity of 317,000 gallons, located on Great Hill. Distributing mains are of cast iron and service pipes are of wrought iron lined with cement.

The advice of the State Board of Health to the town of Rockport relative to the use of this pond as a source of public water supply may be found on pages 45-47 of the annual report for 1893.

A further communication from the State Board of Health to the town of Rockport relative to the pollution of the water of the pond by waste matters from a glue factory may be found on page 65 of the annual report for 1894.

## RUTLAND.

## RUTLAND.

The advice of the State Board of Health to the town of Rutland relative to taking the water of Muschopauge Lake as a public water supply may be found on page 46 of this volume. The results of the analyses of two samples of water collected from the lake are given below.

*Chemical Examination of Water from Muschopauge Lake, Rutland.*

[Parts per 100,000.]

| Number. | Date of Collection. | APPEARANCE. |            |        | RESIDUE ON EVAPORATION. |                   | AMMONIA. |             |            |            | Chlorine. | NITROGEN AS |           | Oxygen Consumed. | Hardness. |

Odor, very faintly vegetable, and in the last sample also disagreeable. The odor became stronger on heating. — The samples were collected from the lake.

*Microscopical Examination.*

No organisms were found in the first sample; in the second, an insignificant number was found.

## WATER SUPPLY OF SALEM AND BEVERLY.

The capacity of the sources of water supply of the cities of Salem and Beverly was increased in 1895 by the construction of a reservoir on Longham Brook and a conduit line to convey the water from this reservoir to Wenham Lake. The area of the Longham Brook Reservoir is 43 acres, and its capacity about 55,000,000 gallons. It is long and narrow, its length being 6,500 feet and its average width a little less than 300 feet. Its greatest depth is about 8.5 feet. The area flowed contained considerable meadow land, and was prepared for the storage of water by clearing away the trees and bushes, but the soil was not removed. The drainage area of Longham Brook, above the dam, is about 3.3 square miles, and it contains a small population.

The pipe leading from the reservoir to Wenham Lake is 36 inches in diameter and 4,900 feet in length. Its upper end is 5 feet below the high-water mark of Wenham Lake. It discharges into the lake at a point about 200 feet from the easterly shore, near the outlet, and

SALEM AND BEVERLY.

set below high water. At the time of introducing water from the Wenham Brook Reservoir into Wenham Lake, Jan. 23, 1895, the level in the lake was 19.27 feet below high-water mark, and on May 18, 1895, the reservoir became full for the first time since April 29, 1891.

Analyses of samples of water from Wenham Lake and Longham Brook Reservoir are given below.

As will be seen by the table of averages by years, the average color of the water in Wenham Lake in 1895 was much greater than in previous years.

*Chemical Examination of Water from Wenham Lake, in Beverly and Wenham.*

\* June to December.

NOTE to analyses of 1895: Odor, generally vegetable, rarely none. — The first two samples were collected from faucets at the pumping station, and the others from the lake.  
For monthly record of height of water in this lake, see page 290.

\* June to December.

† January to May.

‡ March and September.

§ August.

|| July.

¶ June and July.

NOTE to analyses of 1895: Odor, none. — The samples were collected from a faucet at the pumping station while pumping.

*Microscopical Examination.*

No organisms were found in the first sample; in the last sample an insignificant number was found.

**SHEFFIELD.****SHEFFIELD.**

The advice of the State Board of Health to H. S. Andrews and others, of Sheffield, relative to taking the water of certain springs in that town for a public water supply may be found on page 46 of this volume. The analyses of samples of water collected during the investigation of the proposed sources of supply are given below.

*Chemical Examination of Water from Various Sources in Sheffield.*

[Parts per 100,000.]

| 13615   | Jan. 7              | V. slight.  | Cons.             | .75    | 7.95                            | 2.60                 | .0058    | .0252       | .0236      | .0016           | .13       | .0180          | .0001     | .7839            | 4.7       |

Odor of the first sample, none; of the others, very faintly vegetable. On heating, the odor of No. 13615 became decidedly vegetable and unpleasant. — The samples were collected as follows: No. 13583, from Smith's spring, near the junction of two brooks above the road from Sheffield to Hartsville; No. 13617, from Clark's Brook, just below the junction of three small brooks, a short distance north of Smith's spring; No. 13618, from Pool Brook, below the springs and just above the road to Hartsville; No. 13616, from Iron Brook, just above Three-mile Pond; No. 13615, from Iron Brook, below Three-mile Pond and just below a small mill-pond furnishing power for a saw-mill.

*Microscopical Examination.*

The total number of organisms per cubic centimeter found in these samples was as follows: No. 13583, 1; No. 13617, 19; No. 13618, 18; No. 13616, 24; No. 13615, 55.

**SHIRLEY.**

The advice of the State Board of Health to the town of Shirley relative to taking water from Leatherboard Pond in that town as a public water supply may be found on pages 46 and 47 of this volume. The results of analyses of samples of water from several sources in the town, collected during the investigation of proposed sources of supply, are given below.

## SHIRLEY.

\* Where more than one sample was collected in a month the mean analysis for that month has been used in making the average.

† These analyses were made by Prof. William R. Nichols, for the city of Springfield, from samples collected about once a week, between July 1, 1876, and Sept. 30, 1877.

‡ June to December.

§ January to September.

|| May to December.

**NOTE** to analyses of 1895: Odor, vegetable and mouldy or unpleasant, becoming stronger during the latter half of the year. — The samples were collected from the reservoir 2 or 3 feet beneath the surface.

For monthly record of height of water, see page 306.

## STOUGHTON.

## WATER SUPPLY OF STOUGHTON.

The advice of the State Board of Health to the town of Stoughton relative to an additional supply of water for the town may be found in pages 47-50 of this volume. Analyses of samples of water collected during the investigation for an additional supply may be found on page 316 of the annual report for 1894.

## WATER SUPPLY OF SWAMPSCOTT AND NAHANT. — MARBLEHEAD WATER COMPANY.

In 1895 the sources of supply of this company were increased by the construction of temporary works for drawing water from a system of ten tubular wells located a short distance east of the Swampscott station, in the angle formed by the main line of the Eastern Division of the Boston & Maine Railroad and the Marblehead branch. The wells are in the vicinity of a small tributary of Stacy's brook, which flows through this territory, and are in a line parallel to the main line of the Eastern Division. They are 12 feet apart in the line, and range in depth from 30 to 47 feet. These wells are from 800 to 1,000 feet distant from the wells of the Marblehead Water Company in Paradise Road. Between Aug. 6 and Nov. 2, 1895, about 14,500,000 gallons are said to have been drawn from this source for the supply of the towns.

\* June and September.

† January and May.

‡ December, two samples.

NOTE to analyses of 1895: Odor, generally faintly vegetable; sometimes none. In May the odor was distinctly oily on heating. — The samples were collected from the pond at the intake of the Taunton Water Works.

\* September.

† May.

‡ December, two samples.

NOTE to analyses of 1895: Odor, generally faintly vegetable, sometimes none. The odor generally became stronger on heating. — The samples were collected from the pond near the gate-house of the Taunton Water Works.

\* June to December.

For notes to analyses of 1895: Odor, generally vegetable; in August and September, decidedly disagreeable. — The samples were collected from the filter-basin.

\* June to December.

NOTE to analyses of 1895: Odor, vegetable, sometimes also mouldy. — The samples were collected from the river, opposite the filter-basin of the Taunton Water Works.

*Microscopical Examination.*

The average number of organisms per cubic centimeter found in these samples was 79.

## UXBRIDGE.

## WATER SUPPLY OF UXBRIDGE.

## WALPOLE.

The advice of the State Board of Health to the town of Walpole relative to the introduction of a public water supply from the ground in the valley of Low Brook, a short distance above its junction with the Neponset River, may be found on pages 50 and 51 of this volume. The analysis of a sample of water taken from test wells in the vicinity of the brook, below Washington Street, is here given.

Works for supplying the town of Walpole with water taken from the ground in this vicinity were nearly completed at the end of 1895.

\* Where more than one sample was collected in a month the mean analysis for that month has been used in making the average.

† June to December.

‡ January to May.

§ July.

NOTE to analyses of 1905: Odor, none. — The samples collected in January, February and October were taken from the filter-basin, and the other samples from a faucet at the pumping station.

**Microscopical Examination.**

*Oreothrix* was present in seven of these samples, the highest number found in any sample being 88, in December. No. 4164 was not examined. No organisms were found in the other samples.

NOTE to analyses of 1895: Odor, generally none; on September 4 and December 17, faintly vegetable; in October, faintly oily. — The samples were collected from a faucet in a house in the easterly part of Watertown.

*Microscopical Examination.*

Orenothrix was found in eight of these samples, the highest number being 640 in the last sample, and the next highest 76, in No. 14990.

\* September.

† October.

‡ July.

§ June and October

|| July and August.

NOTE to analyses of 1895: Odor of the first sample, none; of the second, faintly unpleasant, disappearing on heating. — The samples were collected from the well at Williams Spring.

*Microscopical Examination.*

No organisms.

## WENHAM.

## WENHAM.

The advice of the State Board of Health to the town of Wenham relative to the use of water from Pleasant Pond in that town as a public water supply may be found on pages 51 and 52 of this volume. The results of the analysis of a sample of water from this pond are given below.

*Chemical Examination of Water from Pleasant Pond, Wenham.*

[Parts per 100,000.]

\* June to December.

† January to May.

‡ July, two samples.

§ January, March, May and July.

|| February, May and August.

NOTE to analyses of 1895: Odor, none when cold. On heating, a distinctly unpleasant odor was developed in the last sample. — The samples were collected from a faucet at the pumping station.

*Microscopical Examination.*

An insignificant number of organisms was found in each of these samples.

**WESTBOROUGH.**

A communication from the selectmen of Northborough to the State Board of Health relative to the pollution of Little Chauncy Pond by the sewage of the Westborough Insane Hospital, and the advice of the State Board of Health to the trustees of the Westborough Insane Hospital relative to the disposal of the sewage from this institution may be found on pages 70 and 71 of this volume.

Analyses of samples of water from Chauncy and Little Chauncy ponds are given below.

*Chemical Examination of Water from Chauncy Pond, Westborough.*

Odor of the first sample, faintly vegetable, becoming stronger on heating; of the second sample, distinctly disagreeable. — The first sample was collected from Chauncy Pond at its outlet, and the second from Little Chauncy Pond at its outlet. The samples were collected during an investigation relative to the alleged pollution of Little Chauncy Pond by sewage from the Westborough Insane Hospital.

## WESTON.

The advice of the State Board of Health to the petitioners for incorporation as the Weston Water and Electric Company relative to taking a water supply for the town of Weston from springs in that town may be found on pages 52 and 53 of this volume. The results of analyses of samples of water collected from tubular wells near the source of Cherry Brook and from tubular wells near Central Avenue are given in the following table.

*Chemical Examination of Water from Tubular Test Wells in Weston.*

[Parts per 100,000.]

| Number. | Date of Collection. | APPEARANCE.       |                 |        | Residue on Evaporation. | AMMONIA. |             | Chlorine. | NITROGEN AS |           | Oxygen Consumed. | Hardness. | Iron. |

No. 14574. No organisms.

## WEST SPRINGFIELD.

## WATER SUPPLY OF WEST SPRINGFIELD.

In the spring of 1895 the works for supplying West Springfield with water were enlarged by the construction of a pipe line to divert the water from springs in the valley of Block Brook into the brook supplying West Springfield Reservoir.

The water of the springs is collected in a small wooden collecting well located on the easterly side of Block Brook, about three-quarters of a mile above the point where it is crossed by the Westfield road. The water flows by gravity from the well to the brook which supplies the West Springfield Reservoir.

## WATER SUPPLY OF WEYMOUTH.

*Chemical Examination of Water from Great Pond, in Weymouth.*

Odor, none. — The sample was collected from the brook, above the site of a proposed reservoir.

*Microscopical Examination.*

Fungi, Molds, 2.

## WINCHENDON.

The advice of the State Board of Health to the town of Winchendon with regard to the use of water from the ground in Prentiss Meadow as a source of water supply for the town may be found on pages 54 to 57 of this volume.

## WATER SUPPLY OF WINCHESTER.

During the last two years there has been a marked increase in the amount of chlorine present in the water of North Reservoir, which is shown in the table of averages by years of chemical examinations of water from this source, given below. This increase is probably due to the increase in population upon the portion of the watershed of the reservoir within the village of Stoneham. It was found by examination, in 1895, that this portion of the watershed contained 400 people.

**NOTE** to analyses of 1895: Odor, generally distinctly vegetable, frequently becoming stronger on heating. In April the odor was decidedly oily on heating. — The samples were collected from the reservoir, above the dam.

There is no way of drawing water directly from this reservoir for the supply of the town. The overflow from it passes into the South Reservoir.

## WINCHESTER.

\* Where more than one sample was collected in a month the mean analysis for that month has been used in making the average.  
 † June to December.

NOTE to analyses of 1895: Odor, none. — The samples were collected from the filter-gallery.

*Microscopical Examination.*

An insignificant number of organisms was found in the samples collected in January, February, May and October, and no organisms in the other samples.

## WOBURN.

## WATER SUPPLY OF WORCESTER.

In the latter part of 1894, the Lynde Brook Reservoir becoming nearly exhausted, a temporary connection was made between this Reservoir and Kettle Brook, and water was drawn from the latter source for the supply of the city. Early in 1895 the city of

## WORCESTER.

Worcester decided to make Kettle Brook a permanent addition to its water supply system, and laid a 30-inch cast iron pipe conduit from the Kent Reservoir, on Kettle Brook, to the Lynde Brook Reservoir.

Above Kent Reservoir, on Kettle Brook, are three other reservoirs, known as the Mann Reservoir, Bottomly Pond and the Arnold Reservoir. Analyses of water from the Lynde Brook and Holden storage reservoirs and from the reservoirs on Kettle Brook are given in the tables which follow.

The advice of the State Board of Health to the city of Worcester relative to the use of Kettle Brook as an additional source of water supply for the city may be found on pages 57 and 58 of this volume.

LEICESTER SUPPLY. — *Chemical Examination of Water from Lynde Brook Storage Reservoir.*

\* June to December.

NOTE to analyses of 1895: Odor, generally faintly vegetable; in January, September, October and November, distinctly vegetable. On heating, the odor became stronger and also mouldy. — The samples were collected from the reservoir near the gate-house, about 1 foot beneath the surface. For record of heights of water in this reservoir, see page 356.

\* June to December.

NOTE to analyses of 1895: Odor, generally faintly vegetable, rarely unpleasant, frequently stronger on heating. In April, the odor was disagreeable on heating; in May, unpleasant and oily. — The first sample was collected from the reservoir at the end of the 30-inch pipe through the dam; the second, at the outlet below the dam; and the others, from the reservoir at the gate-house, 1 foot beneath the surface.

For record of heights of water in this reservoir, see page 356.

## WORCESTER.

HOLDEN SUPPLY. — *Microscopical Examination of Water from the Tutnuck Brook Storage Reservoir.*

**WRENTHAM.**

The advice of the State Board of Health to G. H. Bacon and others of the village of Plainville, in the town of Wrentham, relative to taking the water of the Ten Mile River as a source of public water supply for the village, may be found on page 58 of this volume.

The advice of the State Board of Health to the town of North Attleborough relative to taking water from Ten Mile River for a supply of the town of North Attleborough and the village of Plainville may be found on page 35 of the annual report for 1894, and analyses of water from this source may be found on page 268 of the same volume.

## EXAMINATION OF RIVERS.

---

---

## EXAMINATION OF RIVERS.

---

Regular monthly examinations have been made during the year 1895 of the waters of the Blackstone, Deerfield, Hoosac, Housatonic, Merrimack, Nashua, Neponset, Saugus, Taunton and Ware rivers, and occasional examinations of other rivers in the State. A special examination of the Blackstone River, similar to that made in 1891, was made during the week of September 4-11. A special examination of the Neponset River was made in the drier portion of the year, in connection with investigations of the sanitary condition of the river and the Fowl Meadows, made under direction of chapter 83 of the Resolves of 1895. Examinations were also made of the Charles River at Milford and a small tidal stream known as Crane's River at Danvers, in consequence of complaints as to their sanitary condition.

Most of the results of these examinations will be found arranged alphabetically by rivers in the following pages, but some of them are given on preceding pages, in connection with the examination of water supplies, under the names of towns where the samples were collected, as follows:—

|                                          | PAGE |

| Taunton at Taunton, . . . . .            | 315  |

### BLACKSTONE RIVER.

The regular monthly examinations of the Blackstone River have been continued since June, 1887, and the average results for each calendar year and for the six months of each year from June to

**BLACKSTONE RIVER.**

November, as well as the detailed analyses for 1895, are given in the tables which follow.

During the year ending Nov. 30, 1895, an average of 15,700,000 gallons per day of mingled sewage and brook water, taken from the Mill Brook channel, were treated at the Worcester Precipitation Works, by the addition of about 1,030 pounds of lime per 1,000,000 gallons of sewage, the effluent and the excess of the flow of Mill Brook over the amount treated being discharged into the river. The first of the following tables is taken from the report of the superintendent of sewers of the city of Worcester for the year ending Nov. 30, 1895, and contains the monthly averages of analyses of sewage and effluent and the per cent. removed by treatment.

The special examination of the river was, as nearly as practicable, a repetition of the examination made in July, 1891, and, like that examination, was made at a time of low flow in the stream, in order that the results of the examinations might be comparable. The advice of the State Board of Health to the town of Millbury, relative to the pollution of the Blackstone River by the sewage and sewage effluent from the city of Worcester, may be found on pages 67-69 of this volume.

**WORCESTER SEWAGE PURIFICATION WORKS.***Abstract of Analyses of Sewage and Effluent.*

NOTE. — Monthly averages are made from daily analyses of sewage and effluent. The daily sewage samples consist of forty-eight portions taken half hourly. Sewage samples are taken as nearly as possible in proportion to the amount of sewage being received at the time of sampling. Effluent samples consist of twenty-four portions taken hourly.

\* Where more than one sample was collected in a month the mean analysis for that month has been used in making the average.

Odor, generally musty, frequently disagreeable or offensive. The iron was determined in the first five samples, the average amount being .0756. — The samples were collected from the canal leading from the upper dam of the Calumet Woolen Company to the mill, just before the water passed the screens.

*Microscopical Examination.*

The number of organisms found in these samples varied from 38 to 1034 per cubic centimeter, and averaged 401, *Zooglaea* being generally the most abundant, and averaging 354.

Odor, musty and frequently also disagreeable. The iron was determined in the first five samples, the average amount being .0714. — The samples were collected from the river, just above the dam in the village of Millville.

*Microscopical Examination.*

The number of organisms found in these samples varied from 131 to 909 per cubic centimeter, and averaged 398, *Zoëglæa* being generally the most abundant, and averaging 250.

## SPECIAL EXAMINATION OF THE BLACKSTONE RIVER AND WORCESTER PRECIPITATION WORKS IN SEPTEMBER, 1895.

The examination was made during the week ending Sept. 11, 1895, and was conducted as nearly as possible in the same manner as the examination made in July, 1891, described on page 267 of the report of the State Board of Health for 1891.

The method of collecting the sewage of Worcester and conveying it to the precipitation works remains the same as in 1891. Nearly all of the sewage of the city is discharged into Mill Brook, the channel

**BLACKSTONE RIVER.**

of which has practically been converted into a sewer, having an outlet into the Blackstone River at Quinsigamond Village. The main sewer leading to the precipitation works leads out of the Mill Brook channel near its lower end, and under ordinary conditions the whole flow of Mill Brook is diverted into the sewer by means of a dam, but at times a portion of the flow of the brook passes over the dam and enters the river without treatment.

In addition to the sewage of the city of Worcester, Mill Brook receives the natural drainage from a watershed of about 12.5 square miles, and its flow is consequently subject to great fluctuations. The character of the sewage of Worcester has been fully described in previous reports. Its composition is very variable, both on account of the fact that the sewage is mingled with the water of Mill Brook and on account of the large amount of manufacturing sewage which it receives, and which contains, at times, large amounts of iron salts discharged from the iron wire works in the city.

At the time of the examination in 1891 the normal capacity of the precipitation works was about 5,000,000 gallons per day, and during the examination a little over 6,000,000 gallons per day of sewage from the Mill Brook sewer was treated at the works. A much larger amount than this was conveyed to the works, but the excess was discharged untreated through a by-pass, and entered the river with the effluent. The works were enlarged in 1893, and the new works, which are said to have a capacity of 15,000,000 gallons per day, and to be capable of treating with good results a somewhat larger quantity, are thought to be of sufficient capacity to take the whole flow of Mill Brook under ordinary conditions.

The amount treated during the examination in 1895 averaged about 13,000,000 gallons per day, somewhat over twice the amount treated at the works during the previous examination, and all of the mingled sewage and brook water conveyed to the works was treated, the by-pass being closed.

The general results of the examinations of 1895 are shown in the tables which follow, while the detailed results are shown in tables beginning on page 376. For convenience in comparing the results of the examination of 1895 with the examination in 1891, the general results for the latter examination are reprinted, as far as is practicable, in the tables of general results which follow. The total

**BLACKSTONE RIVER.**

volume flowing in the various channels during each examination is given in the table on page 374. From this table it will be seen that the average flow in Mill Brook channel was somewhat greater in 1895 than in 1891, and that a very small proportion of the flow of Mill Brook was discharged into the river without treatment, as compared with the volume discharged in this way in 1891. The discharge of sewage directly into the river during the examination of 1895 was caused partly by leakage past the dam and partly by a shower which began at about 10 P.M. on the night of Monday, September 10, and caused the water in Mill Brook to overflow the dam. The total flow of the river below the precipitation works averaged 26,830,000 gallons per day in 1895, as compared with 35,840,000 gallons per day in 1891.

The amount of lime per 1,000,000 gallons used for the purification of the sewage during the week of the examination was considerably in excess of the average amount used during the year, and the purification of the sewage attained was greater than is ordinarily attained in the operation of the works. The results of the examination show that the condition of the river below the place where the effluent from the Worcester precipitation works is discharged, and in the town of Milbury, was practically the same as at the time of the special examination in 1891.

**BLACKSTONE RIVER.**

*Comparison of Analyses of Sewage and Effluent from the Worcester Precipitation Works during the Week ending July 29, 1891, and the Week ending Sept. 11, 1895.*

NOTE. — The bacteriological examinations were made Sept. 15, 1891, and Oct. 12, 1895.

**BLACKSTONE RIVER.**

*Comparison of Analyses, made during the Week ending July 29, 1891, of the Water of the Blackstone River, from a Point just below the Precipitation Works at Worcester to Millville. This Table represents the Portion of the River where the Pollution of the Water is decreasing as the Distance from Worcester increases.*

NOTE. — The bacteriological examinations were made Sept. 15, 1891.

## BLACKSTONE RIVER.

*Comparison of Analyses, made during the Week ending Sept. 11, 1895, of the Water of the Blackstone River, from a Point just below the Precipitation Works at Worcester to Millville. This Table represents the Portion of the River where the Pollution of the Water is decreasing as the Distance from Worcester increases.*

**BLACKSTONE RIVER.**

In the following tables are given the detailed results of the examinations of 1895.

As already stated, the samples were taken in the same manner and at the same places as in 1891. In collecting the samples of sewage for chemical analysis one bottle was filled every six hours, and its contents were made up of twelve equal half-hourly collections. The samples of effluent were collected in the same way, but, as the amount of sewage being treated required about six hours for its passage through the tanks, the samples of effluent were taken six hours later than the corresponding samples of sewage. In collecting the samples from the river above and below the precipitation works three bottles were filled every twenty-four hours, each bottle being made up of two or three equal portions. From other points on the river and its tributaries only one sample per day was collected, but wherever it was practicable this sample was made up of from two to four equal portions.

## BLACKSTONE RIVER.

\* These determinations were made upon a mixture of equal parts of water from all the samples.

Odor, musty. — The samples were collected from the river, just above the bridge, in the village of Millville. Each sample was made up of two equal portions, one being collected at 9 A.M., and one at 3 P.M.

Odor of the first sample, faintly vegetable; of the last, distinctly vegetable and musty. — The first sample was collected at the dam opposite the pumping station of the Milford Water Company; the last, at the railroad bridge half a mile below Milford.

The samples were collected in connection with an investigation of the pollution of the stream by sewage from Milford.

Odor of the first sample, none, becoming distinctly vegetable on heating; of the second, disagreeable; of the third and fifth, distinct of manufacturing waste; of the fourth and sixth, faintly musty; of the last, unpleasant. — The samples were collected as follows: No. 15580 from Crane's Brook at the point where it is crossed by the railroad at Tapleyville and above factories in Danvers; No. 15532 from Crane's Brook about 1,000 feet below tannery; No. 15533 from Crane's Pond at the railroad bridge near the lower end; Nos. 15520 and 15534 from Crane's River just below dam at tide mill, the first when the tide was half out and the last at low tide; Nos. 15519 and 15535 from the Essex Branch River below Danversport, the first when the tide was half out and the last at low tide.

These samples were collected in connection with an investigation of the pollution of the stream by manufacturing refuse.

Odor of the first sample, distinctly vegetable; of the second, distinctly vegetable and disagreeable; of the third, distinctly tarry; of the last, decidedly tarry. — The first sample was collected from French River above Webster, just above the mouth of Mill Brook; the second, from Mill Brook, near its confluence with French River; the third, from a brook entering French River just below Merino Village in Dudley; the last, from French River at the first railroad bridge over the river below the line between Massachusetts and Connecticut.

These samples were collected in connection with an investigation relative to a proposed system of sewerage and sewage disposal for the town of Webster.

\* March to December.

NOTE to analyses of 1895: Odor, musty. — The samples were collected from the river.

## MERRIMACK RIVER.

The usual monthly examinations of the water of this river opposite the intakes of the Lowell and the Lawrence Water Works have been continued during 1895, the detailed results of which may be found on pages 204 and 191 of this volume. A comparison of the analyses made at these two places during the year is given in the following table: —

**MERRIMACK RIVER.**

*Table comparing the Analyses above Lowell with those above Lawrence, 1895.*

\* Decrease.

The average flow of the river at Lawrence, for twenty-four hours, during the days on which samples were collected, was for the above periods, respectively, at the rate of 9,148, 9,948, 7,931, 5,433, 8,126, 5,459 and 11,634 cubic feet per second.

Odor of the first two samples, faintly vegetable and mouldy; of the last two, distinctly vegetable. — The samples were collected from the river, a short distance below Hunt's Falls. The first and third samples were made up of several equal portions collected at different points in the north half of the river; the second and fourth were made up of several equal portions collected at different points in the south half of the river.

Odor, distinctly vegetable and unpleasant. — The samples were collected from the river, just above Hale's Island. The first and third samples were made up of several equal portions collected at different points in the north half of the river; the second and fourth were made up of several equal portions collected at different points in the south half of the river.

\* Where more than one sample was collected in a month the average analysis for that month has been used in making the average.

† Four samples on September 17.

‡ Five samples in July and August.

§ August and October.

|| August, October and November.

¶ July to December.

NOTE to analyses of 1895: Odor, generally musty and sometimes disagreeable; in September, vegetable. — The samples were collected from the river at the railroad bridge, a short distance above its mouth.

## NASHUA RIVER.

*Chemical Examination of Water from the Quinepoxet River in Holden.*

\* Where more than one sample was collected in a month the mean analysis for that month has been used in making the average.

† Four samples on September 17.

‡ Four samples in July and August.

§ August and October.

|| August, October and November.

¶ July to December.

NOTE to analyses of 1895 Odor, generally musty and sometimes disagreeable; from July to September, generally vegetable. — The samples were collected from the river at the Atherton bridge, a short distance above its mouth.

## NEPONSET RIVER.

## NEPONSET RIVER.

An investigation of the condition of the Neponset River was made in August and September, 1895, and the results of the examination of samples of water from many points on the main river and its tributaries are given below. A similar investigation was made in 1891,

*Chemical Examination of Water*

[Parts per 100,000.]

\* These analyses were made at the Lawrence Experiment Station.

The samples were collected as follows: No. 16381, from the Neponset River where Main Street crosses it, just above the village of Walpole; No. 16382, at Stetson's dam, just below the village of Walpole; No. 16383, from the mill-pond of the paper-mill of F. W. Bird & Son, in East Walpole; No. 16384, at the Washington Street bridge in East Walpole, just below the paper-mill of F. W. Bird & Son; No. 16385, at the dam of the paper-mill of Hollingsworth & Vose, which is the next below the paper-mill of F. W. Bird & Son; No. 16386, about 100 feet below the paper-mill of Hollingsworth & Vose; No. 16387, at the next dam below the mill of Hollingsworth & Vose, at Water Street; No. 16388, at the Moore Street bridge in Norwood, about 100 feet above the brook which conveys the drainage from Winslow's Tannery to the river; No. 16389, from the brook which conveys the drainage from Winslow's Tannery to the Neponset River, about 100 feet above its junction with the river; No. 16390, from the Neponset River, about 100 feet below the brook from Winslow's Tannery; No. 16391, at the dam of the Printing-Ink Works of Geo. H. Morrill & Co., Pleasant Street, Norwood; No. 16392, from the Neponset

## NEPONSET RIVER.

the results of which were given on pages 319-336 of the annual report for that year.

Both examinations were made at a time of low flow in the river, and a comparison of the analyses indicates that the condition of the river was generally worse in 1895 than at the time when the examination was made in 1891.

## SUMMARY OF WATER SUPPLY STATISTICS.

During the year 1895 a public water supply was introduced for the first time into the towns of Barre, Longmeadow, Millbury, Monson and Rockport, and important additions to many of the existing works were made, to increase the capacity of existing sources of supply.

The following table gives a classification by population of cities and towns having and not having public water supplies December 31, 1895; the populations are taken from the census of 1895:—

| POPULATION<br>(1895).  | Number of<br>Places of Given<br>Population<br>having a Pub-<br>lic Water<br>Supply. | Total<br>Population of<br>Places<br>in Preceding<br>Column. | Number of<br>Places of Given<br>Population<br>not having a<br>Public<br>Water Supply. | Total<br>Population of<br>Places<br>in Preceding<br>Column. |
|------------------------|-------------------------------------------------------------------------------------|-------------------------------------------------------------|---------------------------------------------------------------------------------------|-------------------------------------------------------------|
| Under 500, . . . . .   | 0                                                                                   | 0                                                           | 36                                                                                    | 13,287                                                      |
| 500-1,000, . . . . .   | 3                                                                                   | 2,323                                                       | 56                                                                                    | 43,481                                                      |
| 1,000-1,500, . . . . . | 9                                                                                   | 10,650                                                      | 38                                                                                    | 46,593                                                      |
| 1,500-2,000, . . . . . | 7                                                                                   | 12,115                                                      | 32                                                                                    | 55,861                                                      |
| 2,000-2,500, . . . . . | 10                                                                                  | 19,990                                                      | 14                                                                                    | 31,074                                                      |
| 2,500-3,000, . . . . . | 6                                                                                   | 16,873                                                      | 12                                                                                    | 32,618                                                      |
| 3,000-3,500, . . . . . | 10                                                                                  | 32,515                                                      | 7                                                                                     | 22,599                                                      |
| 3,500-4,000, . . . . . | 5                                                                                   | 18,219                                                      | 1                                                                                     | 3,509                                                       |
| 4,000-4,500, . . . . . | 7                                                                                   | 34,516                                                      | 2                                                                                     | 3,548                                                       |
| Above 4,500, . . . . . | 97                                                                                  | 2,089,816                                                   | 1                                                                                     | 6,039                                                       |
| TOTALS, . . . . .      | 154                                                                                 | 2,237,017                                                   | 199                                                                                   | 268,166                                                     |

From the totals given in the preceding table it will be seen that of the 353 cities and towns in the State 154, or 43.6 per cent., have a public water supply, and the total population of the places supplied represents 89.5 per cent. of the total population of the State. The number of people to whom a public water supply is available is somewhat less than the total population of the municipalities supplied, but the difference is not large. There are now but 11 towns having, by the

census of 1895, a population exceeding 3,000 which are not provided with a public water supply; these are given in the following table:—

| TOWNS.                   | Population in 1895. | TOWNS.                | Population in 1895. |
|--------------------------|---------------------|-----------------------|---------------------|
| Blackstone, . . . . .    | 6,039               | Pepperell, . . . . .  | 3,321               |
| Winchendon,* . . . . .   | 4,490               | Dudley, . . . . .     | 3,203               |
| Barnstable, . . . . .    | 4,055               | Chelmsford, . . . . . | 3,162               |
| North Andover, . . . . . | 3,569               | Dartmouth, . . . . .  | 3,107               |
| Sutton, . . . . .        | 3,420               | Deerfield, . . . . .  | 3,007               |
| Tewksbury, . . . . .     | 3,379               |                       |                     |

\* Works for the supply of this town were under construction at the end of 1894.

In the following table the various water supplies are classified according to the dates when a fairly complete system of supply was first introduced into a city or town:—

| YEARS.                          | Number of Places Supplied. | YEARS.           | Number of Places Supplied. |
|---------------------------------|----------------------------|------------------|----------------------------|
| Previous to 1850, . . . . .     | 6                          | 1891, . . . . .  | 5                          |
| 1850-1859, inclusive, . . . . . | 4                          | 1892, . . . . .  | 1                          |
| 1860-1869, inclusive, . . . . . | 10                         | 1893, . . . . .  | 3                          |
| 1870-1879, inclusive, . . . . . | 44                         | 1894, . . . . .  | 3                          |
| 1880-1889, inclusive, . . . . . | 68                         | 1895, . . . . .  | 5                          |
| 1890, . . . . .                 | 5                          | TOTAL, . . . . . | 154                        |

During the year 1895 the cities of Gloucester and Newburyport took possession of the works which were formerly owned by water companies. At the end of the year all of the 32 cities in the State, having an aggregate population of 1,616,632, owned their water works. Of the 123 towns having a public water supply, 77, with a total population of 407,806, own their works, while 46, having a total population of 212,579, are supplied by private companies. The total population in both cities and towns owning works is 2,240,438, against 212,579 in those supplied by private companies.

The growing tendency in recent years toward municipal control of water supplies is indicated by a comparison of the preceding

figures with similar figures for 1890. At that time 5 of the 28 cities in the State having public water supplies and 50 of the 109 towns were supplied by private companies. The total population of these cities and towns was 318,319, or 16 per cent. of the total population supplied, while in 1895 only 9.5 per cent. of the total population supplied was supplied by private companies.

The following table gives statistics with regard to the consumption of water in the cities and towns in this State where such records are kept. The consumption per inhabitant has been obtained by dividing the average daily consumption by the total population of the city or town in 1895, and consequently is somewhat less than the amount used per consumer, because there are in all cities and towns some who do not use the public water supply. This difference is most marked in towns containing villages to which the public water supply has not been extended, and in towns where the works have been in operation but a short time and where water has not come into general use. In some towns the population during the summer months is much greater than is shown by the census returns, and in such cases the consumption per inhabitant as given in the table is somewhat higher than it would be if allowance should be made for the increased population in summer.

*Statistics relating to the Consumption of Water in Various Cities and Towns.*

## RAINFALL.

The rainfall for the year 1895 was very slightly less than normal, the deficiency being 0.63 of an inch. There was an excess of rainfall in the months of April, July, October and November, and a deficiency in all the remaining months, the greatest deficiency occurring in February. The greatest excess occurred in the months of October and November. An exceptionally heavy rainfall occurred in the eastern part of the State from October 12 to 14, the greatest amount recorded being 8.49 inches at Framingham. The distribution of rainfall was such as to cause a very low flow in the streams in the latter part of August, in September and in the earlier portion of October. The average rainfall in Massachusetts, as deduced from long-continued observations in various parts of the State, is 45.30 inches. In the following table is given the normal rainfall in each month in 1895 and departures from the normal : \* —

## FLOW OF STREAMS.

The flow of the -streams of the State during the year 1895, as indicated by the flow of the Sudbury River, was a very little greater than the average for the past twenty-one years. In order to show the relation between the flow of the Sudbury River during each month in 1895 and the normal flow of the same river, as deduced from observations for twenty-one years from 1875 to 1895, inclusive, the following table has been prepared.

The area of the watershed of the Sudbury River above the point where its flow is measured is 75.2 square miles.

*Table showing Average Monthly Flow of Sudbury River for the Year 1895, in Cubic Feet per Second per Square Mile of Drainage Area, also Departures from the Normal Flow.*

| MONTH.               | NORMAL FLOW.                                 | ACTUAL FLOW                                              | EXCESS OR DE-                                             |

The next table shows the weekly fluctuations, during 1895, in the flow of the two streams most carefully measured, namely, the Sudbury and the Merrimack. The flow of these streams, particularly the Sudbury, will serve to indicate the condition of other streams in eastern Massachusetts.

In the annual report of the State Board of Health for the year 1890 (pages 338 to 340) a table, taken from the annual reports of the Boston Water Board, was printed, giving the records of rainfall upon the Sudbury River watershed and its yield, expressed in inches in depth on the watershed (inches of rainfall collected), for sixteen years, from 1875 to 1890, inclusive. The corresponding records for the years 1891 and 1892 were given in the annual report for 1892, and the records for the years 1893 and 1894 in the annual reports for those years. For convenience, the records from 1891 to 1894, inclusive, are reprinted in the following table, together with the record for 1895 and an average for the whole twenty-one years : —

## FLOW OF STREAMS.

The flow of the streams of the State during the year 1895, as indicated by the flow of the Sudbury River, was a very little greater than the average for the past twenty-one years. In order to show the relation between the flow of the Sudbury River during each month in 1895 and the normal flow of the same river, as deduced from observations for twenty-one years from 1875 to 1895, inclusive, the following table has been prepared.

The area of the watershed of the Sudbury River above the point where its flow is measured is 75.2 square miles.

*Table showing Average Monthly Flow of Sudbury River for the Year 1895, in Cubic Feet per Second per Square Mile of Drainage Area, also Departures from the Normal Flow.*

In the annual report of the State Board of Health for the year 1890 (pages 338 to 340) a table, taken from the annual reports of the Boston Water Board, was printed, giving the records of rainfall upon the Sudbury River watershed and its yield, expressed in inches in depth on the watershed (inches of rainfall collected), for sixteen years, from 1875 to 1890, inclusive. The corresponding records for the years 1891 and 1892 were given in the annual report for 1892, and the records for the years 1893 and 1894 in the annual reports for those years. For convenience, the records from 1891 to 1894, inclusive, are reprinted in the following table, together with the record for 1895 and an average for the whole twenty-one years : —

## FLOW OF STREAMS.

The flow of the streams of the State during the year 1895, as indicated by the flow of the Sudbury River, was a very little greater than the average for the past twenty-one years. In order to show the relation between the flow of the Sudbury River during each month in 1895 and the normal flow of the same river, as deduced from observations for twenty-one years from 1875 to 1895, inclusive, the following table has been prepared.

The area of the watershed of the Sudbury River above the point where its flow is measured is 75.2 square miles.

*Table showing Average Monthly Flow of Sudbury River for the Year 1895, in Cubic Feet per Second per Square Mile of Drainage Area, also Departures from the Normal Flow.*

The next table shows the weekly fluctuations, during 1895, in the flow of the two streams most carefully measured, namely, the Sudbury and the Merrimack. The flow of these streams, particularly the Sudbury, will serve to indicate the condition of other streams in eastern Massachusetts.

In the annual report of the State Board of Health for the year 1890 (pages 338 to 340) a table, taken from the annual reports of the Boston Water Board, was printed, giving the records of rainfall upon the Sudbury River watershed and its yield, expressed in inches in depth on the watershed (inches of rainfall collected), for sixteen years, from 1875 to 1890, inclusive. The corresponding records for the years 1891 and 1892 were given in the annual report for 1892, and the records for the years 1893 and 1894 in the annual reports for those years. For convenience, the records from 1891 to 1894, inclusive, are reprinted in the following table, together with the record for 1895 and an average for the whole twenty-one years:—

*Rainfall Received and Collected on the Sudbury River Watershed.*

| MONTH.                         | 1891.     |                     |                     | 1892.     |                     |                     | 1893.     |                     |                     | 1894.     |                     |                     | 1895.     |                     |                     | MEAN FOR 21 YEARS,<br>1873-1893. |                     |                     |

The Sudbury River records are particularly valuable as a basis for estimating the yield of other watersheds in Massachusetts, both on account of the accuracy with which the measurements have been made during the whole twenty years, and the absence of abnormal conditions which would unfavorably affect the results. It is therefore thought advisable to publish in the following table those portions of the records relating to the yield of this watershed for each of the twenty years; and in doing so the flow from the watershed is expressed in gallons per day per square mile, instead of inches in depth of rainfall collected, in order to render the table more convenient for use in estimating the probable yield of watersheds used as sources of water supply.

*Yield of the Sudbury River Watershed in Gallons per Day per Square Mile.\**

\* The area of the Sudbury River watershed used in making up these records included water surfaces amounting to about one per cent. of the whole area, from 1875 to 1878 inclusive, and subsequently increasing by the construction of storage reservoirs to about three per cent. in 1886. The watershed also contains extensive areas of swampy land, which, though covered with water at times, are not included in the above percentages of water surfaces.

\* Precipitation included in that of following day.

If calcium carbonate and chloride were the only salts to be met with, or if calcium and magnesium salts occurred separately in waters, the results would be quantitative ; but, as the salts usually occur mixed in unknown proportions, the figures given under the heading “ hardness ” are accurate only within limits.

As recorded in the reports of the State Board of Health, the figures under “ hardness ” indicate the number of grams of calcium carbonate which, dissolved in 100,000 grams (100 litres) of distilled water, would decompose as much soap as would 100 litres of the water in question. If the mineral salt was magnesium carbonate or calcium sulphate, the figure would be slightly different ; and if two or three of these compounds were present, yet a different figure would be given. Ordinary soaps contain from 23 to 31 per cent. of water, and in combining power have been found to vary from 75 to 90 per cent. of the value of the standard soap used in the determinations, with a tendency to the lower limit. Not to burden this paper with the long series of experiments and calculations made, it may be said that, on an average which includes some wide variations, the weight of soap required to give a lather which will remain five minutes is ten to twelve times the weight of the calcium and magnesium salts.

From the figures under the heading “ hardness,” in the tabulated analyses, an estimate may be made as follows : —

If the hardness of a water is given as 9.0, it means that in 100,000 pounds of water there is, of calcium and magnesium salts, a quantity which gives the same hardness to water which would be given by 9 pounds of calcium carbonate. In order to soften this water for manufacturing purposes about 9 pounds of soda ash will be required, and for laundry purposes about 90 pounds of soap.

Massachusetts is, as regards hardness, exceptionally fortunate in her water supplies. Of 153 sources supplying 143 cities and towns, only 13 per cent. show over 4 parts per 100,000 of hardness, while half of the remaining 87 per cent. have a hardness below 1.5 parts, and 13.7 per cent. of the whole number have a hardness of less than 0.5 of one part. Of the 19 supplies which have a hardness of more than 4, six are between 4 and 5, four are between 5 and 6, three are between 6 and 10, one is between 10 and 15, five are over 15.

## METHODS OF DETERMINATION OF HARDNESS.

1. *By Soap, — Clark's Method.*

When potassium or sodium soap is added to water containing calcium and magnesium salts, the soap is decomposed, and insoluble compounds with the fatty acids are produced.

Upon this decomposition of soap is based the method for the determination of "lime salts" which was perfected and patented by Thomas Clark \* in 1841. Variouslly modified by French, German and English chemists, the principles he formulated proved of general application. He employed sixteen standard calcium carbonate solutions, containing from one to sixteen "degrees of hardness," one degree meaning one grain of calcium carbonate to the imperial gallon. The soap solution was prepared by dissolving hard soap in proof spirits and making up to such a strength that 100 test measures of the standard calcium carbonate solution of 16 degrees of hardness should take 32 test measures of soap solution, a test measure being  $\frac{1}{1000}$  part of a gallon.

Hardness may be temporary, caused by the presence of bicarbonates which are decomposed by boiling heat, with the liberation of carbon dioxide (carbonic acid), or permanent, caused by compounds other than the bicarbonates. In the Clark process the total hardness is determined on the unboiled water and the permanent on the boiled, the difference being the temporary hardness. The total hardness only is given in the results tabulated in the State Board of Health reports.

The solutions used in the laboratory for water analysis are made as follows: —

A standard calcium chloride solution is prepared by dissolving 0.2 gram of Iceland spar in dilute hydrochloric acid in a platinum dish and evaporating to dryness, redissolving in a small amount of water and again evaporating to dryness. This is repeated several times, until all the free acid is removed and a perfectly neutral salt remains which is dissolved in water and made up to one litre. One cubic centimeter then contains calcium chloride equivalent to 0.0002 gram calcium carbonate.

For the preparation of the standard soap solution 100 grams of the best quality of dry, white Castile soap is cut into thin shavings, dissolved in dilute alcohol (500 cubic centimeters alcohol, 96 per

---

\* Clark's Process, Repertory Patent Inventions, 1841.

cent., and 500 cubic centimeters of distilled water) and allowed to stand over night to settle; 100 cubic centimeters of the clear liquid are then made up to two litres, enough alcohol being used to keep all of the soap in solution. Fifty cubic centimeters of the standard solution of calcium chloride, which, according to the table, should take exactly 14.25 cubic centimeters of standard soap, are used to test its strength. The solution thus prepared does not change perceptibly if air has no access to it, and, if used with a siphon burette attached to the bottle, will keep for five or six weeks or longer. It contains 5.2 grams of Castile soap to the litre.

For the standardization of the soap and for the determination of the hardness of any water, 50 cubic centimeters of the water to be tested or of the standard calcium chloride solution are placed in a flask or bottle of 200 cubic centimeters capacity and of a convenient shape, and the soap solution added, two or three tenths of a cubic centimeter at a time, shaking well after each addition, until a lather is obtained which is permanent for five minutes, and covers the entire surface of the liquid with the bottle placed on its side.

The following table gives the hardness corresponding to the number of cubic centimeters of soap solution used in the analyses:—

*Table of Hardness.*

| Volume of Soap<br>Sol. c.c. | Hardness.<br>(Ca CO <sub>3</sub> per<br>100,000.) | Volume of Soap<br>Sol. c.c. | Hardness.<br>(Ca CO <sub>3</sub> per<br>100,000.) | Volume of Soap<br>Sol. c.c. | Hardness.<br>(Ca CO <sub>3</sub> per<br>100,000.) |

The importance of adding the soap solution in small quantities cannot be too strongly emphasized, especially in the presence of magnesium compounds. If much carbonic acid be liberated, it is well to follow the original directions and remove it by suction. It will be observed that the table does not admit of the determination of hardness above 12.5 parts. In case the water under examination requires more than 10 cubic centimeters of the standard soap solution, a smaller portion of 25 cubic centimeters, 10 cubic centimeters, or even 2 cubic centimeters, as the case may require, is measured out and made up to a volume of 50 cubic centimeters with recently distilled water. This will keep the results comparable with each other, although the element of dilution introduces a slight error into the calculation.

## 2. *By Acid, — Hehner's Method.*

Attempts have been made to determine the calcium and magnesium salts by means of standard acid and alkaline solutions instead of by soap. An exhaustive study of the relative practical value of one of these, as compared with the soap method, was made in 1890 in the laboratory of the State Board of Health. A condensed summary of the results is here given.

The standard solutions used are sodium carbonate, 1.06 grams to the litre, one cubic centimeter corresponding to 0.0001 gram calcium carbonate, and sulphuric acid of such a strength that one cubic centimeter will exactly neutralize one cubic centimeter of the standard sodium carbonate (0.98 gram of sulphuric acid to one litre).

For the determination of the temporary hardness, 100 cubic centimeters of the water to be tested, tinted with lacmoid, which is the best indicator to use with surface waters, are heated nearly to boiling in a porcelain dish, and the standard acid added to a neutral reaction. Each cubic centimeter of acid corresponds to one part of calcium carbonate per 100,000.

For the permanent hardness, another 100 cubic centimeters of water are taken, and enough of the standard sodium carbonate solution added to more than decompose the salts of calcium and magnesium, and the whole evaporated to dryness in a platinum or nickel dish. (Glass and porcelain cannot be used, as too large an error is introduced from the alkali dissolved from these substances.) The residue is first treated with boiling distilled water, which has been boiled for a few minutes to remove any carbonic acid, and then

filtered through a small filter which must be well washed, the filtrate tinted with lacmoid and the excess of free alkali determined by the standard acid.\*

The number of cubic centimeters of sodium carbonate used, less the acid used for neutralization, gives the permanent, and the sum of the two gives the total, hardness.

With alkaline waters, with sewage and with some sewage effluents, a correction must be made for the excess of alkaline carbonates; but in these cases the results after correction do not compare as closely with the soap method as do those obtained with the natural waters.

The following tabulated results were obtained by the two methods, which were tried on a number of ground and surface waters and several samples of sewage, in every case the total hardness being given:—

*Surface Waters.*

[Parts per 100,000.]

\* Analyst, vol. viii, 77, 1883.

These two methods were then tried upon three samples of sewage, the results of which show wide differences :—

| PLACE OF COLLECTION. | Total Hardness by Soap. | Total Hardness by Acid. |
|----------------------|-------------------------|-------------------------|
| No. 1, . . . . .     | 4.20                    | 5.80                    |
| No. 2, . . . . .     | 3.90                    | 7.20                    |
| No. 3, . . . . .     | 3.60                    | 5.60                    |

These three samples were strongly alkaline, in every case the acid method giving the higher results.

The extent to which the presence of magnesium salts affects the results is well shown in the following table, which gives not only the total hardness but the amount of each salt which caused it, as deter-

mined by analysis. It is possible by careful manipulation to precipitate the calcium by means of ammonium oxalate, and, after filtering, to determine the hardness due to the remaining magnesium salts.

[Parts per 100,000.]

|                                  | Total Solids. | Ca CO <sub>3</sub> . | Mg CO <sub>3</sub> . | Solids causing Hardness. | Hardness by Soap. |

The foregoing results show that the simpler soap method gives results agreeing fairly well with the more tedious acid method, and it is therefore desirable to retain it for regular use in determining the hardness of waters for domestic use. It has, moreover, the advantage of being a more direct expression of the amount of soap wasted in using a water.

# EXPERIMENTS UPON THE PURIFICATION OF SEWAGE AND WATER AT THE LAWRENCE EXPERIMENT STATION.\*

---

By HARRY W. CLARK, Chemist in Charge.

---

The year 1895 is the eighth that the experimental work of the Lawrence Experiment Station has been continued. The work has been carried on under the general supervision of Hiram F. Mills, A.M., C.E., a member of the State Board of Health. Mr. Geo. W. Fuller, biologist, was in direct charge of the station until August, 1895, when the writer, who had previously been in charge of the chemical department, succeeded Mr. Fuller in charge of the station. Mr. W. R. Copeland is in charge of the biological department, with Mr. Lewis Weinberg as assistant biologist. Mr. F. B. Forbes is assistant chemist. Profs. T. M. Drown and W. T. Sedgwick, of the Massachusetts Institute of Technology, have been, respectively, consulting chemist and biologist, having a general oversight of the chemical and biological investigations.

The investigations at the Lawrence Experiment Station during the year 1895 have been along the same general lines as in previous years, and additional and valuable data upon the subjects of sewage and water purification have been obtained. The question of the permanency of sewage filters and the best methods of management to secure this permanency, preliminary treatment of sewage by different methods to remove sludge before filtration, and different methods of aerating sewage filters to secure the greatest efficiency, quantitative and qualitative, have been studied. In addition to this, studies of the composition of sewage have been continued, and investigations of methods for the disposal or utilization of waste liquors of industrial works have been begun.

The investigations upon water filtration have been directed towards the subjects of high rates of filtration and the effectiveness of shallow

---

\* A full account of the work done at the Lawrence Experiment Station for the years 1888 and 1889 is contained in a special report of the State Board of Health upon the Purification of Sewage and Water, 1890. A similar account for the years 1890 and 1891 is contained in the twenty-third annual report of the Board for the year 1891. Since 1891 the results have been published yearly in the annual reports.

filters compared with deeper, the influence of period of use upon the qualitative and quantitative efficiency of filters, the efficiency of sands of a character not before used, and studies of the operation and results — chemical, bacterial and hygienic — obtained by the Lawrence city filter. A portion of the investigation into the condition of the Neponset River has been carried out by the force employed at the laboratories of the station.

### FILTRATION OF SEWAGE.

The sewage applied to the experimental filters is drawn through a 2.5 inch pipe, 4,300 feet long, from the Lawrence Street sewer at a point just below the main business street of the city and just above the entrance of wastes from the large mills. This sewer drains the streets, houses and stores of the most densely populated section of the city.

When the investigations at the station were begun, the sewage drawn from this sewer was of a composition and strength quite different from the sewage used at the present time. There are a number of reasons for this change, the most important being the use at the present time of *day* sewage only at the station, and a large increase in the number of house connections with the sewer. Low rainfall and a smaller consumption of water per capita also have an influence.

*Table showing Comparison of Average Analyses of Sewage applied to Experimental Filters at Different Periods.*

[Parts per 100,000.]

| PERIOD.              | Free Ammonia. | ALBUMINOID AMMONIA. |          |            | Chlorine. | Oxygen Consumed. | Bacteria per Cubic Centimeter. |
|----------------------|---------------|---------------------|----------|------------|-----------|------------------|--------------------------------|
|                      |               | Total.              | Soluble. | Insoluble. |           |                  |                                |
| 1895, . . . . .      | 4.05          | 1.00                | .28      | .72        | 11.43     | 5.10             | 2,907,000                      |
| 1894, . . . . .      | 3.43          | 0.63                | .26      | .37        | 8.07      | 3.86             | 1,330,000                      |
| 1888-1893, . . . . . | 2.09          | 0.67                | .30      | .37        | 6.64      | 3.64             | 870,000                        |

### COMPOSITION OF SEWAGE AND RESULTS OF ANALYSES OF SEWAGE APPLIED TO EXPERIMENTAL FILTERS.

The above table shows that the sewage of 1894 was stronger than the sewage of the six preceding years, and that during 1895 it was still stronger than in 1894. The quantity of free ammonia

and the numbers of bacteria present have both largely increased, the total albuminoid ammonia is much greater than heretofore, while the quantity of insoluble albuminoid ammonia is nearly double that of any previous year. Analyses of samples of sewage collected directly from the Lawrence Street sewer, at the point where the pipe from the sewer to the station begins, have been made each week during the year. These samples have been collected almost invariably between eight and nine o'clock in the morning, when the strongest sewage of the day is passing through the sewer. The results of the monthly averages of these analyses are given in the next table, and the second table beyond shows the results of the monthly analyses of the regular station sewage. The greater quantity of free ammonia and the lower quantity of oxygen consumed in the station sewage are due to the slow passage of the sewage through the 2.5 inch pipe from the sewer to the station, with the consequent bacterial and chemical changes. It will also be noticed that the sewage taken directly from the Lawrence Street sewer has invariably contained nitrogen in the form of nitrates and nitrites and also free dissolved oxygen, and that these substances have disappeared when the sewage reaches the station.

*Monthly Averages of Analyses of Sewage from the Lawrence Street Sewer.*

On at least four days in each week a bottle of sewage has been taken for analysis from a large tank of sewage at the station, and this sewage is known as the "regular" sewage.

*Monthly Averages of Analyses of Regular Sewage Samples.*

OTHER SAMPLES OF SEWAGE COLLECTED FOR ANALYSIS.

In addition to the sewages represented by the preceding tables, it has been the practice to collect other representative samples for analysis, as follows:—

1. A sample representing an average of all the sewage pumped on each Tuesday of the year.

2. Samples representing an average of all the sewage applied to filters Nos. 1, 6 and 9 A.

3. On each Tuesday of the year a sample of the supernatant liquid, after allowing regular sewage to stand for four hours.

4. On each Tuesday of the year a sample of the supernatant liquid, after treating the regular sewage of the day with sulphate of alumina in the proportion of 1,000 pounds per 1,000,000 gallons, and allowing to stand and settle for four hours.

5. On each Tuesday of the year a sample of the liquid resulting from straining regular sewage through a layer of coke breeze.

Summarizing these results, we find that, by allowing the sewage to settle in barrels for four hours and then drawing a sample for analysis from a faucet half-way between the top and bottom of the barrel, this sample shows a removal of 48.0 per cent. of the organic matter (total albuminoid ammonia) and 31.0 per cent. of the bacteria. By this same treatment, together with the addition of sulphate of alumina, a removal of 63.0 per cent. of the organic matter and 61.0 per cent. of the bacteria has been obtained. By straining sewage through a layer of coke, 54.0 per cent. of the organic matter and 54.0 per cent. of the bacteria have been removed from the entire volume of sewage strained.

## COMPARISON OF THE STRENGTH OF STATION SEWAGE.

Bringing together for comparison the average results of analyses of the several series of samples of untreated sewage, we have : —

## COMPOSITION OF SEWAGE.

During 1895, series of samples of sewage from Framingham, Marlborough and the Worcester State Lunatic Hospital have been taken in continuation of the studies of the strength and composition of the sewage applied to different filtration areas in the State. All chemical samples were treated, immediately upon collection, with mercuric acetate in the proportion of 1 part to 4,000, to kill the bacteria and prevent decomposition between the time of collection and of analysis. A separate sample was taken for the immediate determination of the dissolved oxygen present, and still another set of samples was taken, from which plantings for the determination of the number of bacteria present were made. These samples were all taken during cooler weather in 1895 than in 1894, and, consequently, the percentage of dissolved oxygen present was greater.

It will be noticed that all samples were taken at a point where the sewage entered a settling basin. The special features in regard to the places where samples were taken in 1895 were given in the report for 1894, but, for accurate understanding, are repeated.

*Worcester State Lunatic Hospital.* — Situated on the outskirts of the city, and not connected with the city sewers. Practically all the water entering the sewer passes through a meter on the city service pipes. The number of inhabitants on the day when the series was

taken was 980. The samples were collected, as in 1894, at a man-hole several hundred feet from the buildings, and just above the settling tank through which the sewage passes on its way to the irrigating field. The high temperature of the sewage is due to the fact that a considerable portion of the water supply is used for laundry purposes six days in the week. The sewage is very fresh at the point of collection of samples; that is to say, the mixture of organic pollutions and water has very recently taken place, and, owing to this fact, the sewage uniformly contains nitrogen in the form of nitrates and nitrites, and the proportion of free ammonia to organic nitrogen is very low. In fact, the sewage is so fresh that good and representative samples are collected with difficulty, as the floating matters are not well broken up before reaching the point of collection. The measurements of the flow of sewage were taken from the meter readings giving the volume of water used.

*Marlborough.*—The sewerage system of this city is of the so-called separate type; but, as there are no underdrains beneath the sewers, a considerable volume of ground water enters them. The length of the outfall sewer, from the last lateral to the point where it discharges into the settling tank at the filter field, is about four miles.

The following series of samples was taken October 30, at the man-hole just as the sewage enters the settling tank. Measurements of the rate of flow were made by noting the length of time taken to fill one of the compartments of this tank. Free oxygen was present in the sewage during the entire twenty-four hours.

*Framingham.*—The sewerage system is arranged with underdrains beneath the principal sewers to carry off the ground water. The series was collected October 30, at the point where the sewage enters the collecting basin, about one mile from the village. Free oxygen was present in the sewage during the entire twenty-four hours.

In regard to the tables given, it may be said that the samples analyzed were made up of equal portions of sewage taken at the hours enclosed by brackets. The average analysis given in each case is a simple average of the determinations given, and is not, of course, an exact representative analysis of the sewage of the day.

It is proposed during the coming year to take more frequent samples in each series, and that these samples shall be in some measure proportional to the rate of flow of the sewage.

## Results of Analyses of Samples of Sewage collected Hourly from the Main Sewer at the Worcester State Lunatic Hospital.

This last table shows the relative amounts of the different substances in the average sewage of each place. The average analysis of the Worcester Hospital sewage agrees very closely with the average analysis of the 1894 series. The number of inhabitants of the institution and the total flow of sewage for the day are also nearly identical for both years. With the Marlborough and Framingham sewages the amounts of these various substances are less in almost every instance in 1895 than they were in 1894. This difference is due to the fact that the total daily flow of sewage was greater on the day on which the series were taken in 1895 than it was in 1894. That is to say, the sewage, especially at Marlborough, was diluted by a much larger volume of ground water, owing to recent rains.

The chief points of the analyses to be noticed are that, as in 1894, the amount of organic nitrogen represented by the albuminoid ammonia is a comparatively small and variable per cent. of that found by the Kjeldahl method. This percentage is lowest where the sewage is freshest and the amount of dissolved oxygen highest; where the sewage is most stale, that is, where it has undergone the longest-continued chemical and bacterial action, the percentage is greatest. The percentage which the nitrogen, as free ammonia, forms of the total nitrogen, follows the same general rule.

#### PERMANENCY OF SEWAGE FILTERS.

The permanency of a sewage filter depends upon the maintenance of an equality between the amount of organic matter applied to the filter, and the amount purified and removed in the effluent or escaping into the air in the form of gas, plus the amount removed from the surface of the filter. If a limited area for filtration purposes is a necessity, there is of course more or less accumulation of organic matters upon the surface of the filter or within the upper few inches of the filtering material.

If the sewage is fresh when it flows upon the filter, the organic matter in suspension will not be finely divided and hence will strain out, remain upon the surface of the filter, and can be removed without removing much if any of the filtering material. This removal keeps the filter porous, in good condition, and the dry scum removed decomposes so slowly that it does not create a nuisance. On the other hand, if the sewage is stale when it flows upon the filtering

area, and the sludge or organic matter in suspension is finely divided by the comparatively long-continued mechanical, chemical and bacterial actions through which it has passed, a much larger percentage of this organic matter will pass into the interstices of the filtering material, and, if removed in any way except by being changed into the inorganic form and passing away in the effluent or escaping into the air in the form of nitrogen and carbon gases, a considerable portion of the surface layers of the filtering material will have to be removed also.

During the earlier years of the investigations at this station the sewage applied to the filters was comparatively weak, but fresh; and considerable trouble was experienced, caused by the clogging of the surface of the filters by the crude organic matters of the sewage; and comparatively poor purification was obtained at such times, because of the difficulty with which the sewage passed through these clogged surfaces, and also because of insufficient aëration from the same cause. During latter years the sewage applied to the filters has been stale, and, because of this and the consequent fine division of the sludge, there has not been so much clogging of the surface as formerly, and very little difficulty has been experienced in disposing of the prescribed daily dose of sewage. The sewage applied to the experimental filters contained, on an average, twice as much unoxidized nitrogen during 1895 as during most of the earlier years (see page 446), and hence, although the number of gallons per acre daily applied to the out-door filters has been largely reduced in some instances, the amount of organic matter applied has not been reduced much, if any. This stale organic matter has apparently been worked over to such an extent, during its slow passage through the pipe from the sewer to the station, that it is of a nature more easily attacked by the bacteria in the filter than was the former fresh organic matter. As a result of this, there has not been the steady increase of stored nitrogen and fats in the filters that formerly occurred. The amount of this stored nitrogen present fluctuates according to seasons of high or low nitrification.

*Table showing the Amount of Nitrogen stored in the Sand of Filters Nos 1 and 9 A at Different Periods, calculated from Determinations of Albuminoid Ammonia.*

[Parts per 100,000 by weight of dry sand.]

| DEPTH BELOW SURFACE.<br>(INCHES.) | FILTER NO. 1.  |                |                |                 | FILTER NO. 9 A. |                |                |

| 48, . . . . .                     | 4.3            | 2.5            | 3.0            | 3.8             | 2.6             | 3.0            | 2.4            |
| 60, . . . . .                     | 3.0            | 1.8            | 2.0            | 3.4             | 1.8             | 1.8            | 2.4            |

In this table the amount of nitrogen in the upper six inches of filtering material is not given, as the method of spading over the surface of the filters to this depth at least twice each year makes accurate and representative determinations difficult to obtain; but the analyses made of the sand of this portion of the filters indicated that there was a smaller amount of stored nitrogen in the upper six inches of Filter No. 1 in October, 1895, than in October, 1894, and that the stored nitrogen in the upper six inches of Filter No. 9 A had increased but little, if any.

There has been no removal of clogged sand from any of the large outdoor filters at the station since 1893 (see pages 413 and 414 of report of 1893), and the weekly rakings to the depth of one inch, together with the spading over of the surface spring and fall, keep the filters in such condition that little difficulty is experienced from the inability of the applied sewage to pass below the surface of the filter.

The actual number of gallons of sewage applied to the large filters, one two-hundredth of an acre in area, from their date of construction up to Jan. 1, 1896, is given in the following table:—

| FILTER NUMBER. | Date when Sewage was First Applied. | Actual Number of Gallons Applied. | Gallons per Acre. |
|----------------|-------------------------------------|-----------------------------------|-------------------|
| 1, . . . . .   | Jan. 10, 1888, . . . . .            | 1,077,000                         | 215,400,000       |
| 2, . . . . .   | Dec. 19, 1887, . . . . .            | 499,300                           | 99,860,000        |
| 4, . . . . .   | Dec. 19, 1887, . . . . .            | 362,400                           | 72,480,000        |
| 5, . . . . .   | Sept. 14, 1891, . . . . .           | 665,400                           | 121,080,000       |
| 6, . . . . .   | Jan. 12, 1888, . . . . .            | 664,000                           | 132,800,000       |
| 9 A, . . . . . | Nov. 18, 1890, . . . . .            | 663,700                           | 132,740,000       |

### RESTING.

With the idea of securing the removal of nitrogen from the surface layers of the large outdoor filters, they were allowed to rest during a large portion of the months of October and November, 1894. The weather was very cold for these months, and this prolonged resting resulted in destroying active nitrification in these filters, and as a result the purification obtained by them during the ensuing winter was very poor. Profiting by this experience, the filters were allowed to rest for short periods only, and during warmer weather in October and November, 1895.

It is very doubtful if any resting, except during warm weather, when nitrification is active, is effective in removing nitrogen, but it gives the filter a chance to drain and the top layers of material to dry.

### EFFECT OF WINTER WEATHER.

The first effect of winter weather is the diminution of the activity of the nitrifying organism. This causes the nitrates of the effluent to become low and increases the quantity of free and albuminoid ammonia. If the sewage applied to the filters does not contain an excessive amount of sludge, or organic matters in suspension, it can be applied in such volume as to keep the filter comparatively free from frost; when sludge is present in large quantity, however, a large volume of sewage will tend to clog the surface of the filter by the deposition of this sludge upon the surface. With the concentrated sewage now pumped at the station, a sewage much stronger than the average of the twenty-four hours' flow in the Lawrence Street sewer, this difficulty is quite a factor in the management of the filters. Where settling basins and sludge beds are in operation this difficulty can be, in a measure, overcome.

### AVERAGE PURIFICATION OF SEWAGE BY THE SEVERAL FILTERS IN 1895.

The following table gives the average results obtained by the several filters during 1895. The qualitative efficiency of the filters is shown by the percentage removal of organic matter of the applied sewage, as indicated by the albuminoid ammonia and oxygen consumed:—

*Average Per Cent. of Albuminoid Ammonia, Oxygen consumed and of Bacteria removed from Sewage by the Several Filters, with Average Rates of Filtration, 1895.*

## REMOVAL OF SLUDGE FROM THE SEWAGE.

As the experiments have continued with the consequent accumulation of data concerning the strength and composition of sewage, it has become evident that the sewage pumped at the station and applied to the experimental filters has been stronger during 1895 than the average sewage flowing through the Lawrence Street sewer, and stronger than any sewage treated at the filtration areas at different places in the State. As a matter of fact, the sludge is generally settled out to a considerable extent at the filtration areas, and applied to separate beds. This method has its advantages, as it concentrates the sludge, and keeps a large amount of clogging material from flowing upon the regular filtration beds. This is especially advantageous in winter, as has been mentioned before. Its disadvantages are, that the sludge, so concentrated, is much more offensive than when allowed to flow upon the filtration areas as rapidly as possible, and become exposed in thin layers to the air. In cold weather, however, the accumulation of sludge is less offensive than in warm weather. Studies of different methods of removing sludge from sewage have been continued throughout the year, as follows : —

1. Rapid filtration through coarse gravel, with the aid of a current of air drawn down through the gravel.
2. Rapid filtration through coarse gravel, with the aid of a current of air forced up through the gravel.
3. Rapid filtration through medium coarse coke, with a current of air forced up through the coke.
4. Sedimentation.
5. Chemical precipitation.
6. Straining through coke.

The percentage removal of organic matter, as indicated by the albuminoid ammonia and the oxygen consumed, and of the bacteria, is shown by the following table : —

*Table showing Purification of Sewage by Different Methods of removing Sludge.*

| METHOD.                                                                                                 | Number of Filter. | Effective Size of Sand. | Uniformity Coefficient. | In Operation since | PERCENTAGE REMOVED OF |                  |           |

### COMPARISON OF THE SEVERAL METHODS.

The first method mentioned has been under investigation at the station for several years, and has been exhaustively discussed in the reports of the Board. It is a scientific success, and perhaps, under favorable conditions, could be used practically. The method of aerating the filters at the station is exceedingly costly, as compared with the results secured. The aspirators attached to filters Nos. 15 and 16 are operated with the entire head or pressure of the city water supply, and will, when attached to a tube of mercury, draw the mercury to a height that shows their power to produce very nearly a vacuum. This gives a power sufficient to draw air through the filters of coarse gravel, even when they are very badly clogged with organic matter. These two filters have received sewage at an average rate of about 450,000 gallons per acre daily, and have removed from it the very large percentage of organic matter shown by the table. This organic matter has been largely oxidized or burned up, but not by any means completely, over 20 per cent. of that applied during 1895 being stored in each filter. This storage of organic matter causes sooner or later such a clogging of the filter and poor purification that it must be removed, or the life of the

filter is ended. Removal by continuous aëration without application of sewage to the filter is a slow and incomplete method, and, if the gravel be removed and washed, the labor is considerable and the volume of water used very large.

*Forcing Air up through the Filter.*

On Feb. 1, 1895, an experiment was begun to test the value, estimated by percentage removal of sludge, of filtering sewage through some coarse media at high rates, aided by a current of air forced up through the filtering material.

For this purpose two filters of equal size were constructed, one containing 60 inches in depth of coarse gravel of an effective size of 5.30 millimeters, and the other with the same depth of coke breeze, from which the finer particles had been removed. The outlets of these filters were trapped, and down through the centre of each a pipe was passed, reaching to within 6 inches of the bottom of the filter. To these pipes a fan blower was attached, driven by electric power, the idea being to carry the air to the under-drains of each filter, where it would pass out into the under-drains and be forced up through the interstices of the filtering material. These filters have received sewage at an average rate, during their period of operation, of 608,000 gallons per acre daily. The blowing apparatus used created a current of air that was capable, under the most favorable circumstances and with the fan making 3,600 revolutions per minute, of holding up a column of mercury nearly 3 inches. With the connections and elbow joints necessary to carry the air to the point desired, the force of the current was reduced to one-third of this. During the period of operation of these filters this current of air was never strong enough to move pieces of paper laid upon the surface of the filters, and was only occasionally strong enough to be felt by placing the hand upon the surface. When the surface became badly clogged, the force of the current generated by the open-sided blower was apparently only strong enough to keep a steady pressure of air against the under side of the clogged surface layers of the filter, and there was a constant current of air from the open sides of the blower. The filters used in this experiment were numbered 51 and 52.

*Filter No. 51.*—This filter, one three-thousandth of an acre in area, contained 60 inches in depth of gravel of an effective size of

5.30 millimeters. It received sewage during the period of its operation at an average rate of 608,400 gallons per acre daily, and its effluent contained on an average 37 per cent. of the organic matter of the applied sewage, as shown by the albuminoid ammonia determinations, and 23 per cent., as shown by the determinations of oxygen consumed. Two and eighty-one one-hundredths pounds of organic nitrogen were applied to the filter, 1.15 pounds of organic nitrogen passed away in the effluent, and 0.27 of a pound remained stored in the filter at the close of the experiment. (For details of operation, see page 491.)

*Filter No. 52.*—This filter was of the same depth and area as Filter No. 51, but contained, instead of gravel, coke breeze from which the finer particles had been removed. It was operated in the same manner as Filter No. 51, and received during its period of operation the same volume of sewage. It was a more efficient filter in removing organic nitrogen from the applied sewage than Filter No. 51, but this nitrogen was stored in the filter, as shown by the fact that nitrification was lower than in Filter No. 51. This removal of sludge from the applied sewage was aided by the exceedingly rough surfaces of the pieces of coke.

*Disposal of Effluents of Filters Nos. 51 and 52.*—The effluents of filters Nos. 51 and 52 were, for the comparison of results obtained, each divided into three portions, and applied equally to filters of equal depth and area, but containing different filtering materials; that is, the effluent of Filter No. 51 was applied to Filter No. 53, one twenty-thousandth of an acre in area and containing 60 inches in depth of sand of an effective size of 0.19 millimeter; to Filter No. 55, of the same area and depth, but containing sand of an effective size of 0.40 millimeter; and to Filter No. 57, containing 60 inches in depth of coke breeze. The effluent of Filter No. 52 was applied to three similar filters, — filters Nos. 54, 56 and 58.

The results obtained by this double filtration were not as good as the results obtained by the filters 15 B, 16 B, 12 A combination, as shown by the next table, owing to the comparatively poor purification obtained in filters Nos. 51 and 52. There was no appreciable difference in the operation of these filters, and the qualitative results obtained were very similar, as shown by the table.

The amount of nitrogen stored in the sand filters at the close of the experiment, calculated from albuminoid ammonia determinations, was as follows:—

[Parts per 100,000 by weight of dry sand.]

| DEPTH BELOW SURFACE (INCHES). | Filter No. 53.           | Filter No. 55.           | Filter No. 54.           | Filter No. 56.           |

*Sedimentation.*

At many sewage disposal areas the sewage is allowed to pass through settling tanks, in order that as large an amount of the sludge as possible may settle out; the supernatant liquor then flows to the disposal areas and the sludge to specially prepared sludge beds. The amount of sludge removed by this method varies with the character and strength of the sewage.

During 1892 the continuous experiment at the station showed a removal of 18 per cent., and during 1895 of 48 per cent., of sludge, as indicated by the total albuminoid ammonia. The sewage of the latter year contained much more sludge than the sewage of the former year. A larger percentage of the sludge can generally be removed from fresh sewage than from stale sewage in which the sludge is more finely divided. (For results upon the removal of sludge, see pages 450 and 451.)

*Chemical Precipitation.*

The percentage removal of sludge by means of the addition of chemicals to the sewage, and subsequent sedimentation, depends upon the same factors as in the removal of sludge by sedimentation alone. In both cases the result is a concentration of the sludge in a smaller body of liquid. This resulting concentrated sewage, in volume generally at least one-fourth the original volume, remains to be disposed of. (For results upon chemical precipitation, see pages 450 and 451.)

*Straining through Coke.*

By straining sewage through coke we have removed, during 1895, 54 per cent. of the sludge (total albuminoid ammonia) of the sewage. The sewage has been strained at an average rate of 1,000,000 gallons per acre daily, and the coke strainer has contained from 6 to 8 inches in depth of coke. The coke used is known as breeze, and is the screenings from commercial coke. At the Lawrence gas house, where it is obtained, it is used under the boilers, and called worth one-fourth as much as the steam coal or from \$1.00 to \$1.25 per ton; the amount used has been equal to 10 cubic yards per 1,000,000 gallons of sewage strained, and, as a ton of coke contains about 2.3 cubic yards, the sewage has been purified, to the extent given, at a cost for coke of \$5.43 per 1,000,000 gallons of sewage strained, calling the coke worth \$1.25 per ton.

By this method of straining we remove the sludge from the entire body of liquid, and get rid of the concentrated sludge liquor which is a result of sedimentation and chemical precipitation; and it seems probable that the coke is as valuable for combustion after use in the strainer as before.

The following table shows the qualitative and quantitative purification obtained by these different methods for removing sludge, followed by filtration, during 1895:—

*Table showing Total Purification of Sewage by Filtration and a Preliminary Treatment to remove Sludge.*

| METHOD.                                                                                                                | Number of Filter. | SIZE OF SAND.                                          |                         | Average Rate (Gallons per Acre Daily, Six Days a Week). | PERCENTAGE REMOVED OF |                  |           |

### COMPARISON OF RESULTING LIQUIDS.

Comparing the resulting liquids after the treatment of sewage by these various methods of removing sludge, it is noticeable that the organic matter in the liquids after rapid filtration combined with aëration is of a different character from the organic matter in the sewage resulting from the other sludge-removing processes. That is to say, even when the organic matter, as shown by the albuminoid ammonia, is present in quantities as great as in the other partially purified sewages, it has passed through such chemical and biological changes that it develops offensive odors very slowly on standing.

---

### THE DISPOSAL OF WASTE LIQUORS FROM INDUSTRIAL WORKS.

Investigations upon the disposal of waste liquors from the processes of paper making, wool scouring and tanning have been begun.

#### *Paper Making.*

All rags are cleaned before being made into paper by being boiled in a solution of caustic soda, caustic lime, or a mixture of soda ash and lime, to free them from grease, dirt and coloring matters. The resulting liquor is very highly polluted with organic matter and when discharged into a small body of water may create a nuisance. On September 8, a filter was started to see if this waste liquor could be purified by filtration through sand. The liquor applied to the filter is very alkaline, and the results obtained indicate that while a considerable purification may be obtained by filtration through sand, yet the organic matter present is of a nature not easily attacked by the bacteria in the filter and the degree of alkalinity obtained is unfavorable for the growth of the nitrifying bacillus. (For results obtained see page 501.) When, however, this liquor is diluted by the large volume of wash water used in paper making, the resulting dirty water or sewage can in most cases probably be easily purified by filtration. The volume of wash water is very large.

#### *Wool Scouring.*

The condition of wool when first obtained from the sheep's back is such that mordanting and dyeing without removal of the grease, dirt, etc., would be impossible. Besides the mechanically held dirt

the impurities are of a two-fold character, the "wool fat," soluble in ether, and the "wool perspiration," soluble in water. The two are frequently included under the name of the "yolk" or "suint" of the wool.

Wool fat is not a fat as commonly understood, that is, it is not a glycerate. By treating it with boiling alcohol it may be separated into two portions, one soluble and the other insoluble in this liquid. The soluble portion consists mainly of cholesterine and isocholesterine, together with compounds of these bodies with organic acids. The insoluble portion consists mainly of cholesterine and isocholesterine with oleic and fatty acids. Grease and dirt are present on the wool to such an extent that different wools lose from 15 to 75 per cent. by weight in passing through the washing, scouring and rinsing processes. It is the common method to remove these impurities by solutions of alkaline carbonates and soaps. In the centres of the French and Belgian woollen industries the wool is first washed with water, the solution evaporated, and potassium carbonate recovered. This potassium carbonate may be present to the amount of 4 per cent. of the weight of the raw wool. In this country little if anything is done towards recovering the potash salts, the preliminary treatment with water being generally dispensed with. In many places abroad the waste scouring liquors are collected in stone-lined pits and neutralized or acidified by sulphuric acid, and the fatty matters, which rise to the surface, are collected in filter bags and sold. This of course causes a partial purification of the liquor, but all the dirt and a considerable portion of the fatty matter still remain in it. There are very few places in this country, however, where even this partial purification is undertaken, the waste liquor in its entirety being allowed to run into and pollute the neighboring stream. A process of wool cleansing, growing in favor, is one by which the fatty matters are first removed by naphthalene or gasoline and the remaining dirt subsequently removed by the usual scouring process, the fat removed by the first process being a valuable by-product.

Careful calculations have shown that the volume of water used in a wool-scouring plant is about 100 gallons per pound of wool scoured; a small and varying proportion of this volume being directly used in the scouring bowls and the remainder being used for rinsing the wool after scouring.

Beginning September 8, the strong waste liquor from the scouring process has been applied to a filter containing 5 feet in depth of sand

of an effective size of 0.25 millimeter. The rate of application has been equal to about 17,000 gallons per acre daily, and the results so far obtained have made clear that while this liquor can be filtered through sand and a considerable portion of the organic matters removed, yet it is with such difficulty and at such low rates in gallons per acre daily that a preliminary treatment, to remove a large part of the dirt and fatty matters before filtration, is essential. Subsequent filtration of the effluent of this filter improves it little if any, the character of the organic matter and the degree of alkalinity of the original liquor and the effluent being such that the bacteria attack it very feebly. The numbers of bacteria in the liquor and in the effluent are enormous, but the nitrifying bacillus does not seem to develop and the organic impurities are apparently of such a stable character that decomposition and putrefaction take place very slowly.

#### *Removal of Fats and Dirt before Filtration.*

As already mentioned, a certain portion of the fats present in the wool liquor can be collected by the addition of sulphuric acid to the liquor, but a more complete removal of the fats and dirt can be effected by the addition of calcium chloride. This precipitates the fat as a lime soap and the precipitate carries down with it all the dirt in suspension in the liquid, leaving a clear but highly colored solution. It seems probable, and experiments are now under way to test the fact, that, by hot pressing this precipitate, enough fat may be obtained to make the process pay for itself. The clarified liquor is rich in organic matters in solution but they are of the same stable character as before mentioned and pass through 5 feet of sand with very little change.

#### *Tannery Sewage.*

In connection with the investigations in regard to the condition of the Neponset River two experimental filters have been operated at Norwood, Mass., to determine the feasibility of purifying, by filtration through sand, the waste liquors from preparing and tanning hides.

A filter was constructed containing 2 feet in depth of sand, of an effective size of 0.14 millimeter, over gravel under-drains. It was not feasible to have at the place desired a filter with a greater depth of sand, owing to the slope of the land and the necessity of having the sewage run on to the filter by gravity and away from the under-drains in the sewer which carries the tannery sewage to the river.

Sewage was first applied to this filter September 27. The sewage is a mixture of the waste liquors from all the processes carried on in the tannery, and it has been applied to this shallow filter at an average rate of 55,000 gallons per acre daily, and with the results given below.

*Table showing Average Analyses of Sewage applied to and Effluent from the Filter.*

[Parts per 100,000.]

|                     | Free<br>Ammonia. | Albuminoid<br>Ammonia. | Chlorine. | NITROGEN AS |           | Oxygen<br>Consumed. |
|---------------------|------------------|------------------------|-----------|-------------|-----------|---------------------|
|                     |                  |                        |           | Nitrates.   | Nitrites. |                     |
| Sewage, . . . . .   | 3.1000           | 3.1600                 | 312       | .1600       | .0015     | 55.00               |
| Effluent, . . . . . | 2.3400           | .6000                  | 290       | 1.0500      | .0100     | 7.50                |

The sewage is very strong and offensive, being highly charged with decaying animal tissues and the bran added to cause fermentation to take place. It is also highly colored by the different aniline dyes used in coloring the hides, and these coloring matters, after the first few weeks of operation of the filter, failed to be completely removed. The sewage applied to the filter has been almost entirely that resulting from the preparation of the hides, the spent tan liquor forming but a very small proportion of the waste liquors flowing from the tannery. It need hardly be said that tannic acid if applied in any quantity would be very prejudicial to decomposition and nitrification in the filter.

#### *Precipitation with Lime.*

In one of the processes at the tannery a large amount of lime is used, and in consequence of this, there is an almost continuous stream of lime water flowing into and mixing with the remainder of the sewage; and it is evident that, if settling tanks were properly arranged, and the flow of lime water regulated, a large percentage of the sludge could be precipitated out. Preliminary experiments have shown that probably 60 per cent. of the organic matter can be removed in this way, but the resulting supernatant sewage is very rich in organic matter in solution.

A small filter, to which this supernatant sewage is applied at an average rate of 120,000 gallons per acre daily, was started toward the end of the year, and is at the present time, July, 1896, in a

state of active nitrification and giving a clear almost odorless effluent. These experiments have demonstrated that this sewage can be purified by filtration.

#### WORK OF THE FILTERS FOR 1895.

The experimental filters in operation during 1895 have included all in operation at the end of 1894, together with the addition of filters Nos. 51, 52, 53, 54, 55, 56, 57, 58, 59, 60 and 61. Filters 1 to 10 inclusive are out of doors, and are each one two-hundredth of an acre in area; filters 12 to 61 inclusive are within the buildings and are one twenty-thousandth of an acre in area, with the exception of Filter No. 59, which is one ten-thousandth of an acre in area, and filters Nos. 51 and 52, which are one three-thousandth of an acre in area.

##### *Filter No. 1.*

This filter, containing 60 inches in depth of coarse sand of an effective size of 0.48 millimeter, was purifying sewage very poorly at the beginning of the year, owing to the destruction of nitrification by too long continued resting during the cold weather of October and November, 1894. This poor purification continued throughout January and February, and not until the middle of March did the effluent begin to show good oxidation and nitrification in the filter. Observations were made daily during this period of the presence of frost, and efforts made to re-establish nitrification by picking holes in the surface of the filter, to allow the sewage to pass more rapidly below the surface, and by seeking to remove frost by the application of large doses of sewage.

On January 25 the filter was covered with two thicknesses of canvas stretched over a frame, as in previous years, and this cover was removed March 13. On March 23 the surface was spaded over (corresponding to ploughing) to a depth of 4 inches. Good results were obtained from the first of April throughout the remainder of the year. August 20 the surface was raked (corresponding to harrowing) to a depth of 3 inches and on October 22 and November 9 it was spaded over to a depth of 6 inches. On November 15 it was covered for the winter with canvas stretched over a frame. The quantity of sewage applied to the filter was at the rate of 80,000 gallons per acre daily during the first half of the year and 60,000 gallons per acre daily during the last half of the year.

The monthly averages of the weekly analyses of the effluent of this filter are presented in the next table.

*Monthly Averages of Analyses of Effluent of Filter No. 1.*

Sewage applied, 400 gallons six times a week, January 1 to March 31; 200 gallons twelve times a week, April 1 to July 31; 300 gallons six times a week, August 1 to 18; 150 gallons twelve times a week, August 19 to October 21; 150 gallons three times a week, October 22 to 31; 150 gallons twelve times a week, November 1 to December 31. Tank covered with canvas January 25 to March 13, and November 15 to December 31. April 11 to 20, experiment interrupted by freshet. Trap attached to outlet June 19 to July 3, and a trap 18 inches high August 31 to September 27. September 9, trap turned down and effluent pipe flushed out. August 31, white worms found in under-drains, and under-drains flushed out. Surface raked about 1 inch deep each week except twice in February and once in April. Surface dug over 4 inches deep March 23; 3 inches deep August 20 and December 27; 6 inches deep October 22 and November 8. During January, 8½ inches of snow and 3½ inches of ice removed from surface; during March, 2½ inches of snow and ½ inch of ice removed.

*Filter No. 2.*

This filter, containing 60 inches in depth of fine sand of an effective size of 0.08 millimeter, trenched with medium fine sand of an effective size of 0.19 millimeter, had, at the beginning of the year, begun to feel the effects of the prolonged resting during the cold weather of October and November, 1894. The effluent of the filter continued to be of a poor quality during January, February and March, but during April the nitrates were much higher, although the free ammonia was still high. From the beginning of May throughout the remainder of the year the filter was in good condition and the effluent of a satisfactory quality. During the first two months of the year the sewage applied to the filter disappeared

below the surface very slowly, and from February 8 to 18 the trenches remained partially covered with sewage and none was applied. The average rate of application of sewage during these two months was 18,000 gallons per acre daily. During the remainder of the year the approximate rate of application was 38,000 gallons per acre daily. On March 25 the sand of the trenches was removed, the sides of the trenches raked, the fine sand at the bottom of the trenches spaded over 3 inches deep and the sand of the trenches replaced. On September 9 this operation was repeated. The results for the year are shown by the monthly averages of the weekly analyses.

*Monthly Averages of Analyses of Effluent of Filter No. 2.*

Sewage applied, trenches were filled six times a week January 1 to March 26, except three days in January and eleven days in February. Amount of applied sewage varied from 40 to 190 gallons; 200 gallons six times each week, March 26 to October 22; 100 gallons three times a week, October 23 to 31; 200 gallons six times a week, November 1 to December 31. April 11 to 20, experiment interrupted by frost. March 25, sand removed from trenches; sides of trenches raked; bottoms of trenches dug over 3 inches deep; sand thoroughly mixed and replaced in trenches. August 31 to September 6, a trap 18 inches high attached to outlet. September 9, grass and weeds removed from surface of tank; sand removed from trenches; bottoms and sides of trenches scraped and dirty sand piled on middle of tank; sides of trenches raked, and bottoms of trenches dug over 4 inches deep; sand thoroughly mixed and replaced in trenches. Surface of trenches raked 1 inch deep each week, except two omissions in February and one in April. October 22, surface of trenches dug over 3 inches deep. During January, 12½ inches of snow removed from entire surface, 9½ inches of ice from outer trench, and 5½ inches from inner; during February, ½ inch of snow removed from surface, 4½ inches of ice from outer trench and 8 inches from inner; during March, 5 inches of snow removed from surface; during December, 8 inches of snow removed from surface, 1½ inches of ice from each trench.

*Filter No. 4.*

This filter, of fine river silt of an effective size of 0.04 millimeter and containing two trenches of coarse sand of an effective size of 0.48 millimeter, was giving an effluent of a good quality at the beginning of the year, but its surface was in poor condition and disposed of the applications of sewage with difficulty, the average

rate of filtration being only 7,000 gallons per acre daily for the first three months of the year, and from February 6 to 18 inclusive no sewage was applied to the filter. For the remainder of the year the average rate of filtration was 18,300 gallons per acre daily. The nitrates in the effluent were the lowest during March and April, but the ammonias were also low. On March 27 the sand of the trenches was removed, the sides of the trenches raked, the fine sand at the bottom of the trenches dug over to the depth of 3 inches and the coarse sand replaced. This treatment was repeated September 7, at which date a small amount of the dirty sand at the bottom of the trenches was removed and placed upon the surface of the filter. The quality of the effluent was quite satisfactory throughout the year, as shown by the following table, giving the monthly averages of the weekly analyses:—

*Monthly Averages of Analyses of Effluent of Filter No. 4.*

Sewage applied, trenches filled three times a week, January 1 to March 29, except two days in January, six days in February, and three days in March. Quantity of applied sewage varied from 40 to 190 gallons; 200 gallons three times a week, March 30 to October 21; 100 gallons three times a week, October 22 to November 1; 200 gallons three times a week, November 2 to December 31. April 11 to 20, experiment interrupted by freshet. August 31 to September 6, a trap 18 inches high attached to outlet. March 27, sand removed from trenches; sides of trenches raked and bottoms of trenches dug over to a depth of 3 inches; sand thoroughly mixed and replaced in trenches. September 7, grass and weeds removed from surface of tank; sand removed from trenches; bottoms and sides of trenches scraped and dirty sand piled on middle of tank; sides of trenches raked and bottoms dug over 4 inches deep; sand thoroughly mixed and replaced in trenches. Surface of trenches raked 1 inch deep once in January, not at all in February, three times in March, and once each week during the remainder of the year. October 22 and December 27, surface of trenches dug over 3 inches deep. During January, 12½ inches of snow removed from entire surface, 12½ inches of ice from outer trench, and 7½ inches of ice from inner; during February, 2 inches of snow removed from surface, 10 inches of ice from outer trench and 5 inches from inner; during March, 4 inches of snow removed from surface, 1 inch of ice from outer trench and ½ inch from inner; during December, 8 inches of snow removed from entire surface.

*Filter No. 5.*

This filter, of fine gravel stones of an effective size of 1.40 millimeters, took the applied sewage without difficulty at an average rate of 76,000 gallons per acre daily during the first three months of the year, but the effluent was, until the middle of March, of a very poor quality, owing largely to the destruction of nitrification toward the end of 1894. From the middle of March until the end of the year the effluent was of as good a quality as could be expected from a filter of this coarse material entirely under-drained and only 5 feet in depth. The free ammonia of the effluent was high throughout the year, a natural result of the quick passage through the filter of sewage very high in free ammonia. The filter was spaded over to the depth of 4 inches March 4, raked 3 inches deep August 21, and spaded to a depth of 6 inches October 22. The results of the monthly averages of the weekly analyses are given in the following table:—

Sewage applied, 400 gallons six times a week, January 1 to March 31; 200 gallons twelve times a week, April 1 to July 31; 300 gallons six times a week, August 1 to 21; 150 gallons twelve times a week, August 22 to October 21; 150 gallons three times a week, October 22 to 31; 150 gallons twelve times a week, November 1 to December 11; 300 gallons six times a week, December 12 to 18; 150 gallons twelve times a week, December 19 to 31. April 11 to 20, experiment interrupted by freshet. August 30 and 30, white worms found in under-drains, and under-drains flushed out. August 31 to December 17, a trap 18 inches high was attached to outlet. September 9, trap turned down and pipe flushed out. Surface raked 1 inch deep each week, except two omissions each in January and February. March 23, surface spaded 4 inches deep; October 22, 6 inches deep. During January, 14½ inches of snow and 8½ inches of ice removed from surface; during February, 8½ inches of snow and 8½ inches of ice removed; during March, 5½ inches of snow removed; during December, 9½ inches of snow and ½ inch of ice removed.

*Filter No. 6.*

This filter contains 44 inches in depth of mixed coarse and fine sand of an effective size of 0.35 millimeter. In common with some of the other outdoor filters it was giving an effluent of a very poor quality at the beginning of the year, owing to the destruction of nitrification during the cold weather of October and November, 1894. Efforts were made to re-establish nitrification in the filter by keeping its surface in such a condition that it would dispose of the applied sewage freely, but nitrification did not become active until the warmer weather of March came to its aid. From the first part of April throughout the remainder of the year the nitrates of the effluent were very high and the quality of the effluent exceedingly satisfactory, especially considering the strength of the applied sewage and the shallowness of the filter. Sewage was applied to the filter at an average rate of 59,800 gallons per acre daily for the first three months of the year and the average rate of application from April 1 until the end of the year was 58,500 gallons per acre daily. The surface of the filter was spaded over 4 inches deep on March 23, raked to a depth of 3 inches August 20 and spaded over to a depth of 6 inches October 22. The following table shows the work of the filter for the year:—

Sewage applied, 300 gallons six times a week, January 1 to October 22; 150 gallons three times a week, October 23 to 31; 300 gallons 6 times a week, November 1 to December 31. April 11 to 20, experiment interrupted by frost. August 31 to September 11, a trap 18 inches high was attached to outlet pipe. September 9, trap turned down and pipe flushed out. Surface raked 1 inch deep each week, except two omissions in January and two in February. March 23, surface spaded over 4 inches deep; August 20, 3 inches deep; October 22, 6 inches deep. During January, 11½ inches of snow and 8½ inches of ice removed from surface; during February, 17 inches of snow and 8½ inches of ice removed; during March, 8 inches of snow removed; during December, 8 inches of snow and ½ inch of ice removed.

*Filter No. 9 A.*

This filter contains 5 feet in depth of sand of an effective size of 0.17 millimeter. At the beginning of the year nitrification had almost ceased in the filter, owing to the prolonged resting during the latter part of 1894. The surface of the filter was in fairly good condition and the applied sewage passed below the surface as readily as is usual in cold winter weather. On February 1 the filter was covered with canvas stretched over a frame, but nitrification did not become re-established until warmer weather began in March. Throughout the remainder of the year the filter was in good condition, nitrification was active and the effluent of a satisfactory quality. As the cold weather of fall and early winter began, the process of nitrification became somewhat less active and the ammonias of the effluent greater, but the physical condition of the filter was excellent and it was taking the applied sewage readily. The character of the effluent tends to show that a filter of this depth, entirely under-drained and containing sand of this grade, cannot, with the quantities of sewage applied, cause an entire transformation of such large quantities of nitrogen as are now present in the sewage, in the form of free ammonia and organic nitrogen, into nitrogen in the form of nitrates, except during those periods of warm weather when nitrification is most active. The filter was spaded over 4 inches deep March 23, raked to a depth of 3 inches August 20, and spaded over to a depth of 6 inches September 7 and November 8. The following table shows the monthly averages of the weekly analyses : —

*Monthly Averages of Analyses of Effluent of Filter No. 9 A.*

Sewage applied, 400 gallons six times a week, January 1 to July 31; 300 gallons six times a week, August 1 to October 21; 150 gallons three times a week, October 22 to 31; 300 gallons six times a week, November 1 to December 31. April 11 to 20, experiment interrupted by freshet. Tank covered with canvas February 1 to March 13. Effluent pipe plugged August 30 and 31, and August 31 to September 4. A trap 18 inches high attached to outlet pipe August 31 to September 14. September 9, trap turned down and pipe flushed out. Surface raked 1 inch deep each week, except once in January and twice in February. March 23, surface spaded 4 inches deep; August 20, 3 inches deep; September 7, October 22 and November 8, 6 inches deep; November 20, 3 inches deep. During January, 15 inches of snow, and 8½ inches of ice removed from surface; during February, 1 inch of ice removed; during March, 2½ inches of snow removed; during December, 8 inches of snow and 2 inches of ice removed.

*Filter No. 10.*

This filter, one two-hundredth of an acre in area, contains 5 feet in depth of a mixed coarse and fine sand of an effective size of 0.35 millimeter. No gravel or under-drains are beneath the sand except directly above and around the outlet pipe. A partition extending 3 feet below the surface separates that quarter of the surface farthest removed from the under-drains from the remainder of the surface. To this quarter of the surface farthest from the under-drains the sewage is applied and, during January, the rate of application was 160,000 gallons per acre daily. The filter had not rested during November, 1894, and nitrification was fairly active but steadily decreased and the free ammonia of the effluent was high. The applied

sewage contained a large percentage of organic matter in suspension, and this, together with the extremely cold weather and the consequent depth of frost in the filter, clogged the surface of the filter to such a degree that the applied sewage was disposed of with difficulty, and on February 1 the rate of application was reduced to 80,000 gallons per acre daily and increased to 160,000 gallons per acre daily April 1. The character of the effluent deteriorated, however, during February, but improved rapidly in March and was fairly satisfactory during the remainder of the year. During the winter the sewage was applied to a trench 1 foot in depth and on March 23 this trench was filled and the surface of the filter levelled. Later in the spring it seemed probable that sub-surface clogging was taking place in the filter, and the quarter of the surface to which sewage is applied was dug over to the depth of 18 inches on May 18. This was followed by greatly improved nitrification. On October 22 the surface of the filter to which sewage is applied was spaded over to the depth of 6 inches. The following table gives the results of the monthly averages of the weekly analyses:—

*Monthly Averages of Analyses of Effluent of Filter No. 10.*

Sewage applied, 200 gallons six times a week, January 1 to 31; 100 gallons six times a week, February 1 to March 31; 200 gallons six times a week, April 1 to July 31; 160 gallons six times a week, August 1 to October 22; 75 gallons three times a week, October 23 to 31; 160 gallons six times a week, November 1 to December 31. April 11 to 20, experiment interrupted by a freshet. August 31 to September 6, a trap 18 inches high was attached to outlet pipe. October 12, grass and weeds removed from that part of surface which is not flooded, and sand dug over 6 inches deep. That part of the surface to which sewage is applied has been raked once each week, except once in January and twice in February. May 18, that part of surface to which sewage is applied was spaded over 18 inches deep; August 9, 8 inches deep; October 22, 6 inches deep; December 27, 8 inches deep. During January, 16½ inches of snow and 3 inches of ice removed from that part of surface to which sewage is applied; during February, 30½ inches of snow and 5½ inches of ice removed; during March, 5½ inches of snow removed; during April, ¼ inch of snow removed; during December, 8 inches of snow and ¾ inch of ice removed.

*Filters Nos. 12 A, 15 B and 16 B.*

Filter No. 12 A contains 60 inches in depth of sand of an effective size of 0.19 millimeter, and filters Nos. 15 B and 16 B contain 65 inches in depth of gravel stones of an effective size of 5.40 millimeters. These three filters were first put in operation in July, 1892, and the effluents of filters Nos. 15 B and 16 B have uniformly been applied to Filter No. 12 A.

The actual rates of filtration in gallons per acre daily of these three filters during their period of operation up to Jan. 1, 1896, have been as follows:—

|                                             | 1892.   | 1893.   | 1894.   | 1895.   |

Since the first part of 1893, filtration in filters Nos. 15 B and 16 B has been aided by a current of air drawn down through the filters. It is seen from the table above that Filter No. 12 A has not been able to take the entire volume of effluent of the gravel-stone filters during the past three years, and that its quantitative capacity has gradually decreased. Beginning March 24, 1893, the surface of Filter No. 12 A was scraped on an average once in five days during the year, to relieve clogging, and the average depth of sand removed at each scraping was 0.24 inch. The removed sand was washed and replaced. From Jan. 1, 1894, to June 19, 1894, the surface of this filter was scraped whenever necessary, to remove clogging, and the removed sand was not replaced.

The average interval between scrapings up to June 19 was seventeen days, and the average depth scraped was 0.17 of an inch, equivalent to 12 cubic yards of material removed per 1,000,000 gallons of partially purified sewage filtered. From this date until the end of 1894 the surface was raked to a depth of 3 inches twice each week and spaded over 6 inches deep September 6 and October 27, and 8 inches deep on November 21. The filter was in good condition at the beginning of 1895 and the same method of treatment

was continued, the surface being raked to a depth of 3 inches twice each week during the year and spaded over to a depth of 6 inches March 15, May 25, July 17 and August 3. Towards the end of September the filter began to be badly clogged, and was spaded over to a depth of 6 inches six times between September 21 and November 1, and to a depth of 8 inches seven times between November 1 and December 12. The quantitative capacity of the filter steadily decreased however, and on December 7 the surface sand to a depth of 7 inches was removed, washed and replaced. This sand, before washing, contained 76.10 parts of nitrogen by weight in 100,000 parts of dry sand, and after washing, 7.90 parts. Following this treatment the applied sewage was disposed of more readily. It seems probable that though the organic matters stored in the sand are not present in large quantities, they are of a fatty nature not easily acted upon bacterially; are, in fact, the organic matters that have been partially worked over while passing through the gravel filters and the more easily attacked portion removed. The effluent of Filter No. 12 A has been of most excellent quality throughout the year.

Filters Nos. 15 B and 16 B have received sewage during their period of operation at the rate in gallons per acre daily given in the preceding table. From the time the aspirators were attached to the filters until Sept. 1, 1894, a current of air was constantly drawn down through the filters at the rate of about one gallon in every four minutes. At this date the method of aëration was changed, so that the filters were aerated only at night for twelve or sixteen hours. Better results followed this method of aëration, and the volume of air supplied was sufficient, as shown by examination of the effluents for dissolved oxygen, it being almost uniformly present. The surfaces of these two filters were not disturbed until July, 1893, a year after they were first put in operation, but since that date they have been raked and spaded over very often. During 1895 they have been raked over once each week to a depth of 3 inches and spaded over 6 or 8 inches deep when the condition of the surface required it. There has been an accumulation of organic matter in the filters each year, and to such an extent that, in order to continue them in service, Filter No. 15 B had to be flushed out twice during 1894 by applying city water under pressure for six hours to the outlet pipe, the wash water flowing away over the top of the filter. Filter No. 16 B was given a similar flushing out during 1894, and later the

filtering material was entirely removed and replaced after washing. February 1, 1895, the entire filtering material of Filter No. 15 B was removed, washed and replaced, and after the high water of the Merrimack River in April, the upper 6 inches of gravel in both filters was removed and washed, to free it from river silt. The aspirator of Filter No. 16 B has been allowed to run from nine P.M. to five A.M. each night during the year, and that of 15 B for the same hours until September 2, since when it has been allowed to run from nine to eleven P.M. Aëration for two hours has sufficed to give a good effluent, but there has undoubtedly been a larger percentage of organic matter stored in the filter than there would have been with longer continued aeration each day. In conclusion it seems reasonable to say that the rate of application of sewage and the period of aëration should be so defined that flushing out the filters, or removing and washing the filtering material, would seldom be necessary, as these operations in themselves create a very large volume of sewage to be in some manner disposed of.

The quality of the effluents of these filters during 1895 is shown by the following tables :—

*Monthly Averages of Analyses of Effluent of Filter No. 12 A.*

Effluent of filters Nos. 15 and 16 applied 24 times a week, January 1 to July 9; thirty times a week, July 10 to August 2; twenty-four times a week, August 3 to September 21; thirty times a week, September 22 to November 7; none applied October 18 to 26; once a week, November 8 to 24; twenty-four times a week, November 25 to December 31. April 11 to 24, experiment interrupted by freshet. Surface raked 3 inches deep twice each week. February 16, 6 inches of sand removed; sand replaced in tank March 1. February 18 and August 3,  $\frac{1}{2}$  inch of sand removed. Sand disturbed 6 inches deep on following dates: February 16, March 15, May 25, July 17, August 3, September 21, October 5, 10, 12, 18 and 28. Sand disturbed 8 inches deep on the following dates: November 8, 11, 15, 18, 22, 29 and December 2. December 7, 7 inches of sand removed, washed and replaced in tank.

Sewage applied, 2 gallons seventy-two times a week. No sewage applied, January 4 to 10, January 28 to February 1. April 10 to 20, experiment interrupted by freshet. Filter was aspirated sixteen hours each night, January 1 to March 2, except from January 4 to 10, and January 28 to February 1, when aspirator was run continuously; eight hours a day, March 4 to May 13; fifteen minutes a day, May 14 to June 4; one hour a day, June 6 to 12; eight hours a day, June 13 to August 31; two hours a day, September 2 to December 31. February 1, all the gravel taken out of tank, washed and replaced. March 2, 5 inches of gravel removed from tank. April 20, 6 inches of gravel removed from tank, washed and replaced. Surface raked 3 inches deep once a week. Surface spaded 12 inches deep January 30. December 14, under-drains washed out with city pressure.

Sewage applied, 2 gallons seventy-two times a week. April 10 to 20, experiment interrupted by freshet. Filter aspirated eight hours each night. September 2 to 26, aspirator run at one-quarter regular speed. March 2, 5 inches of gravel removed from tank. April 20, 6 inches of gravel removed from tank, washed and replaced. December 14, under-drains washed out with city pressure. Surface raked 3 inches deep once a week.

*Filter No. 13 A.*

This filter contains 60 inches in depth of medium fine sand of an effective size of 0.19 millimeter, and has received the supernatant liquid from sewage which has been allowed to settle for four hours.

The rate of filtration during the greater part of 1895 has been approximately 160,000 gallons per acre daily. The filter was in good condition at the beginning of the year and was raked to a depth of 3 inches twice each week during the year and spaded over to a depth of 6 inches March 15, July 5, August 24, September 4 and 22, and October 4, 18 and 28. During the first eight months of the year nitrification was active in the filter although the effluent contained free ammonia in considerable quantity, but during September the nitrates of the effluent rapidly decreased and the filter was spaded over repeatedly to a depth of 6 inches, as noted above, but without appreciable effect upon the character of the effluent. On October 28 the gravel under-drains of the filter were flushed out with city water and a large amount of iron which had been deposited upon the gravel was in this way removed. Following this treatment the quality of the effluent rapidly improved, and during November and December the nitrates were the highest and the ammonias the lowest of the year. It seems probable that during September and October there was good nitrification within the filter but that the nitrates of the effluent were reduced to free ammonia while passing through the under-drains of the filter. The following table gives the monthly averages of the weekly analyses:—

*Monthly Averages of Analyses of Effluent of Filter No. 13 A.*

Settled sewage applied, 4 gallons twelve times a week. No sewage applied, October 17 to November 1. April 10 to 22, experiment interrupted by freshet. Surface raked 3 inches deep twice each week. Surface dug over 6 inches deep on the following dates: March 15, July 5, August 24, September 4, 22, October 4, 12, 18 and 23. October 23, under-drains washed out with city pressure.

*Filter No. 14 A.*

This filter contains 60 inches in depth of medium fine sand of an effective size of 0.19 millimeter, and has received since June 1, 1894, sewage which has been strained through a shallow layer of coke. This partially purified sewage has been applied to the filter at an average rate, excluding periods of rest, of 320,000 gallons per acre daily during the year. The surface of the filter has been raked to a depth of 3 inches twice each week during the year and spaded over to a depth of 6 inches, March 15, August 24 and October 6. The quality of the effluent has been satisfactory throughout the year and has invariably contained high nitrates. The filter was in excellent condition at the end of the year. The following table gives the monthly summary of the analyses made during the year:—

Four gallons of sewage, strained through coke, applied twenty-four times a week. No sewage applied October 21 to November 1. April 10 to 20, experiment interrupted by freshet. Surface raked 3 inches deep twice each week. Surface dug over 6 inches deep on the following dates: March 15, August 24, October 4, 21 and 28.

*Filter No. 19.*

This filter contains 60 inches in depth of medium fine sand of an effective size of 0.19 millimeter, and has received the supernatant liquid from sewage which has been allowed to settle four hours after treatment with sulphate of alumina at the rate of 1,000 pounds per 1,000,000 gallons. The filter has received this supernatant liquid since Jan. 20, 1893, and the rate of application during 1895 has been, excluding periods of rest, 200,000 gallons per acre daily. Nitrification has been very active in the filter during the entire year, as shown by the high nitrates of the effluent. The albuminoid ammonia of the effluent was comparatively low during the year, and the comparatively high free ammonia was not caused by any clogging of the filter but was the natural consequence of the extremely high free ammonia of the applied sewage. The filter was raked 3 inches deep each week and spaded over 6 inches deep October 28.

Chemically precipitated sewage applied, 5 gallons twelve times each week. No sewage applied October 28 to November 1. April 10 to 20, experiment interrupted by freshet. Surface raked 3 inches deep twice each week. October 28, surface dug over 6 inches deep.

*Filter No. 21 A.*

This filter was started March 19, 1894. A portion of the filtering material was removed during 1894, but on April 1, 1895, the filter was restored to its original depth of 60 inches of fine sifted gravel of an effective size of 1.60 millimeters. Since July 7, 1894, it has had a current of air drawn downward through it, at the rate of about one gallon in four minutes, for ten or twelve hours each night. During 1895 this filter has received sewage during its period of actual operation at the rate of 360,000 gallons per acre daily, except during June and July, when the rate of application was 499,000 and 427,000 gallons per acre daily, respectively. The filter became badly clogged during February and was allowed to rest from February 18 to April 1, with continual aëration. This treatment improved the condition of the filter and restored nitrification. In August clogging again occurred and the filter was allowed to rest, with continuous aëration from August 7 to 21 inclusive. During the remainder of the year the filter was in good condition. The following table gives the results of the monthly averages of the weekly analyses:—

Sewage applied, 2 gallons twelve times a day at intervals of one-half hour, six days in a week, January 1 to August 20;  $1\frac{1}{2}$  gallons twelve times a day from August 21 to December 31. No sewage applied and aspiration continuous, January 5 to 10, January 28 to February 3, February 18 to March 31, May 18 to 31, August 7 to 20. April 10 to 21, experiment interrupted by freshet. Filter aspirated sixteen hours each night. Surface raked 3 inches deep daily January 1 to March 31, and once a week during the remainder of the year. April 1, filter filled to its original depth with washed gravel. April 20, 6 inches of gravel removed, washed and replaced in tank. January 30, surface dug over 12 inches deep. Surface scraped on January 4 and April 1.

*Filter No. 22 A.*

This filter contained originally 60 inches of fine coke breeze above the usual under-drains. The rate of filtration during 1895 has been 360,000 gallons per acre daily. On account of clogging during February the filter was allowed to rest from February 18 to April 1. The surface of the filter was raked to a depth of 3 inches daily until the period of rest and to the same depth twice each week during the remainder of the year. Up to Nov. 14, 1894, 3.5 inches of the surface coke had been removed, equivalent to 8.6 cubic yards per 1,000,000 gallons of sewage filtered. During 1895 6.1 inches of coke were removed up to November 14, equivalent to 15 cubic yards per 1,000,000 gallons of sewage filtered. With the exception of the months of January and February nitrification in the filter was active throughout the year. The table of monthly averages of the weekly analyses is presented below: —

Sewage applied, 6 gallons eighteen times a week. No sewage applied February 18 to March 31. April 10 to 21, experiment interrupted by freshet. Surface raked 3 inches deep daily, January 1 to 31, and once a week during the remainder of the year. February 1, 3 inches of coke removed, and 3 inches of clean coke put on filter. February 18,  $\frac{1}{2}$  inch of coke removed from filter; November 15, 3.1 inches removed.

*. Filters Nos. 51 and 52.*

Each of these filters is one three-thousandth of an acre in area. Filter No. 51 contains 60 inches in depth of gravel of an effective size of 5.30 millimeters above the usual under-drains, and Filter No. 52 contains 60 inches in depth of coke breeze, from which the finer particles have been removed, above the usual under-drains. The outlets of these two filters have been trapped and they have been aerated by means of a fan blower driven by electric power, as previously described. Beginning February 1, each of these filters received sewage at the rate of 500,000 gallons per acre daily, applied in six doses between 6 A.M. and noon. This rate of filtration and method of application continued until May 2, when the method of application was changed so that twice this volume of sewage was applied in twelve doses between 7 A.M. and 11 P.M., giving a rate of 1,000,000 gallons per acre daily. This continued until June 21. From June 21 to June 25 inclusive the filters were allowed to rest, and on June 26 they were started again, but the rate of application of sewage was reduced to 500,000 gallons per acre daily, applied in six doses between 7 A.M. and 10 P.M. This continued until June 29, when the same quantity of sewage was applied in twelve doses between 7 A.M. and 11.30 P.M. During these first five months of operation of the filters nitrification did not become well established, and although there was a considerable reduction of the free and albuminoid ammonia of the sewage in passing through the filters, it was largely on account of retention and storage in the filters. From July 2 to 7 inclusive, the rate of application was 250,000 gallons per acre daily, and from July 8 to 17 inclusive, the filters were operating very poorly, the method of application was irregular and the average rate was less than 100,000 gallons per acre daily. This low rate improved the condition of the filters and nitrification became established.

From July 18 to August 13 the rate of filtration was 250,000 gallons per acre daily and was applied in three doses between 7 A.M. and 2.30 P.M. From August 14 to September 2 inclusive, the rate of filtration was 500,000 gallons per acre daily, applied in six equal doses between 7 A.M. and 10 P.M., and from September 2 until the end of the experiment, December 10, the rate was 1,000,000 gallons per acre daily, applied in twelve equal doses between 7 A.M. and 11.30 P.M. During the last five months of operation of the filters

nitrification was active within the filters, but the effluents, especially that of Filter No. 51, contained a large amount of free and albuminoid ammonia. The better clarification of the effluent of Filter No. 52 was on account of greater storage of organic matter within the filter.

From February 12 to May 2 the filters were aerated two hours daily, from 2 to 4 P.M. From May 2 to June 1, one and one-half hours daily, divided into half-hour periods, June 1 to 15, six half hours daily, June 16 to July 10, twelve half hours daily, July 15 to August 5, fourteen hours daily. August 6 to 11 the motor was out of order and the average period of aëration was one and one-half hours daily, with no aëration on August 7, 9 and 10. From August 13 to September 3 the filters were aerated fourteen hours daily, and from September 3 until the end of the experiment, with a few exceptions, the filters were aerated two and three-fourths hours daily, in fifteen minute periods, half way between the times of applying the sewage.

*Monthly Averages of Analyses of Effluent of Filter No. 51.*

Sewage applied, 25 gallons thirty-six times a week, February 1 to April 30; 25 gallons seventy-two times a week, May 1 to June 25; 25 gallons thirty-six times a week, June 26 to 28; 12½ gallons seventy-two times a week, June 29 to July 1; 12½ gallons thirty-six times a week, July 2 to 7; 6½ gallons thirty-six times a week, July 8 to 17; 25 gallons eighteen times a week, July 18 to August 13; 25 gallons thirty-six times a week, August 14 to September 1; 25 gallons seventy-two times a week, September 2 to December 10. Blower ran 2 hours six times a week, February 18 to April 30; ¼ hour eighteen times a week, May 1 to June 3; ½ hour thirty-six times a week, June 4 to 14; ½ hour seventy-two times a week, June 15 to July 9; 1½ hours daily, six days a week, July 10 to September 1; 15 minutes sixty-six times a week, September 2 to December 10. February 4, a trap 2 feet high was attached to outlet. March 2, 5 inches of gravel removed from filters 15 and 16, and the whole quantity thoroughly mixed with the top foot of gravel in Filter No. 51. April 15 to 21, experiment interrupted by freshet. Trap washed out once a week after July 22. Surface raked 3 inches deep once a week, April 1 to September 2. Surface dug over 6 inches deep July 10 and November 30.

\* Brown.

Sewage applied, 25 gallons thirty-six times a week, February 1 to April 30; 25 gallons seventy-two times a week, May 1 to June 25; 25 gallons thirty-six times a week, June 26 to 28; 12½ gallons seventy-two times a week, June 29 to July 1; 12½ gallons thirty-six times a week, July 2 to 7; 6½ gallons thirty-six times a week, July 8 to 17; 25 gallons eighteen times a week, July 18 to August 13; 25 gallons thirty-six times a week, August 14 to September 1; 25 gallons seventy-two times a week, September 2 to December 10. Blower ran 2 hours six times a week, February 18 to April 30; ½ hour eighteen times a week, May 1 to June 3; ½ hour thirty-six times a week, June 4 to 14; ½ hour seventy-two times a week, June 15 to July 9; 13½ hours daily six days a week, July 10 to September 1; 15 minutes sixty-six times a week, September 2 to December 10. February 4, a trap 2 feet high was attached to outlet. April 15 to 21, experiment interrupted by freshet. Trap washed out once a week after July 22. August 1 to 4, all the air from the blower passing through tank. Surface raked 3 inches deep once a week, April 1 to September 2. Surface dug over 6 inches deep July 10, November 30, and 12 inches deep July 26.

*Filter No. 53.*

This filter is one twenty-thousandth of an acre in area, and contains 60 inches in depth of sand of an effective size of 0.19 millimeter. From February 1 to May 17 it received the effluent of No. 51 at the rate of 1,000,000 gallons per acre daily. Following this treatment the surface of the filter became so badly clogged by the excessive application of partially purified sewage that the rate had to be greatly reduced and was quite irregular in volume, the average rate from May 17 to July 19 averaging considerably less than 500,000 gallons per acre daily. From this last date until the end of the experiment, December 10, the average rate was 500,000 gallons per

acre daily. During this last period the applied effluent of Filter No. 51 was fairly well purified and contained nitrates in considerable quantity. The filter was allowed to rest from June 21 to 25 inclusive and July 11 to 15 inclusive. The surface was raked 3 inches deep twice each week during April, and beginning May 2, to the same depth daily. The surface was spaded over to a depth of 6 inches May 22, June 3, 13, 20 and November 22. The following table shows the results of the monthly averages of the analyses of the effluent of this filter:—

*Monthly Averages of Analyses of Effluent of Filter No. 53.*

Effluent of Filter No. 51 applied, 16½ gallons eighteen times a week, February 1 to May 1; 12½ gallons twenty-four times a week, May 2 to July 1; from July 2 to 22, amount of applied effluent varied from 2 gallons to 32½ gallons daily; 12½ gallons twelve times a week, July 23 to December 10. February 18, ½ inch of sand removed from surface of Filter No. 12 and thoroughly mixed with top foot of sand in Filter No. 53. April 15 to 21, experiment interrupted by freshet. Surface raked 3 inches deep once a week, April 1 to 22, and daily from April 23 to December 10. Surface dug over 6 inches deep, May 22, June 3, 13, 20, November 22.

#### *Filter No. 54.*

This filter is a duplicate of Filter No. 53, and has received during its period of operation the effluent of Filter No. 52. The effluent was applied at an average rate of 1,000,000 gallons per acre daily until the middle of June, when the surface of the filter became badly clogged. On June 13 the surface was spaded over to a depth of 6 inches and the filter was allowed to rest from June 21 to 25 in-

clusive. The condition of the filter did not improve and the average rate of application of the partially purified sewage was, during July, 356,000 gallons per acre daily. During the remaining period of operation of this filter the applied effluent contained nitrogen, in the form of nitrates, in considerable quantities, and was of such quality that the filter disposed of it at an average rate of 500,000 gallons per acre daily, without difficulty. The surface of the filter was raked to a depth of 3 inches once each week from April 1 until April 23, and after this date to the same depth daily. The surface was spaded over to a depth of 6 inches May 25, June 13, 29 and November 6. The quality of the effluent during the period of operation of the filter is shown by the following table:—

Effluent of Filter No. 52 applied, 16½ gallons eighteen times a week, February 1 to May 1; 12½ gallons twenty-four times a week, May 2 to June 29; from June 30 to July 21, amount of applied effluent varied from 3 gallons to 47½ gallons daily; 12½ gallons twelve times a week, July 22 to December 10. April 16 to 21, experiment interrupted by freshet. Surface raked 3 inches deep once a week, April 1 to 22, and daily from April 23 to December 10. Surface dug over 6 inches deep, May 25, June 13, 29, November 24, December 5.

### *Filter No. 55.*

This filter is one twenty-thousandth of an acre in area, and contains, over the usual gravel under-drains, 5 feet in depth of sand of an effective size of 0.40 millimeter. To this filter the effluent of

Filter No. 51 was applied. The average rate of application during the first five months of operation of the filter was, excluding periods of rest, 1,000,000 gallons per acre daily. The surface of the filter became very badly clogged by this excessive application of partially purified sewage and the filter was allowed to rest from July 3 to 15 inclusive. During the remainder of the year the rate of application was 500,000 gallons per acre daily. The surface of the filter was not disturbed until April; during April it was raked 3 inches deep each week until April 23, and from this last date, until the end of the experiment, to the same depth daily. The surface of the filter was dug over to a depth of 6 inches April 13, May 24, June 7 and 18. The quality of the effluent of the filter is shown by the following table:—

Effluent of Filter No. 51 applied, 10½ gallons eighteen times a week, February 1 to May 1; 12½ gallons twenty-four times a week, May 2 to July 1; none applied July 2 to 15; from July 16 to 22, amount of applied effluent varied from 3 gallons to 25 gallons daily; 12½ gallons twelve times a week, July 23 to December 10. February 18, ½ inch of sand removed from surface of Filter No. 1 and thoroughly mixed with top foot of sand in Filter No. 55. April 15 to 21, experiment interrupted by freshet. May 24, a ½-inch pipe, similar to the ones in filters 15 and 16, was driven down through the center of the filter, and an aspirator attached. Surface raked 3 inches deep once a week, April 1 to 22, and daily from April 23 to December 10. Surface dug over 6 inches deep April 13, May 24, June 7, 18.

*Filter No. 56.*

This filter is in area and construction a duplicate of Filter No. 55, and has had applied to it, during its period of operation, the effluent of Filter No. 52. The rate of application of this effluent was, during the first five months of operation of the filter, approximately 1,000,000 gallons per acre daily. The surface of the filter became quite badly clogged during July and the rate of application was very much reduced, averaging for the month 356,000 gallons per acre daily. From the beginning of August until the end of the experiment the quality of the effluent of Filter No. 52 was much improved, and was disposed of readily by Filter No. 56 at an average rate of 500,000 gallons per acre daily. The surface of the filter was not disturbed until April. During the first three weeks of April it was raked to a depth of 3 inches three times, and beginning April 23, to the same depth daily.

Effluent of Filter No. 52 applied, 16½ gallons eighteen times a week, February 1 to May 1; 12½ gallons twenty-four times a week, May 2 to June 28; from June 29 to July 21, the amount of applied effluent varied from 3 gallons to 47½ gallons daily; 12½ gallons twelve times a week, July 22 to December 10. April 15 to 21, experiment interrupted by freshet. Surface raked 3 inches deep once each week, April 1 to 22, and daily from April 23 to December 10. Surface dug over 6 inches deep, November 23.

*Filter No. 57.*

This filter is one twenty-thousandth of an acre in area, and contains, over the usual under-drains, 5 feet in depth of coke breeze. The effluent of Filter No. 51 has been applied to this filter. During the first five months of its period of operation the rate of application was, approximately, 1,000,000 gallons per acre daily. This rate of application overtaxed the capacity of the filter and its surface became so badly clogged that during July the rate of application was very much reduced and was quite irregular. From the first of August through the remaining months of operation of the filter it disposed of the better purified effluent of Filter No. 51 without difficulty at an average rate of 500,000 gallons per acre daily. The surface of the filter was not disturbed until April. During April the surface was raked to a depth of 3 inches three times up to April 23 and from that date daily throughout the remaining months of the experiment.

Effluent of Filter No. 51 applied, 16½ gallons eighteen times a week, February 1 to May 1; 12½ gallons twenty-four times a week, May 2 to June 23; from June 29 to July 22, the amount of applied effluent varied from 2 gallons to 47½ gallons daily; 12½ gallons twelve times a week, July 23 to December 10. April 15 to 21, experiment interrupted by freshet. Surface raked 3 inches deep once each week, April 1 to 22, and daily from April 23 to December 10.

*Filter No. 58.*

This filter is, in area and construction, a duplicate of Filter No. 57, and has had applied to it during its period of operation the effluent of Filter No. 52. During the first five months of its period of operation the rate of application was, approximately, 1,000,000 gallons per acre daily. This overtaxed the capacity of the filter and during July the rate was much less and quite irregular. From August 1 throughout the remaining months of operation of the filter the average rate of application was 500,000 gallons per acre daily, and the filter disposed of it without difficulty. The surface of the filter was not disturbed until April. During April it was raked to the depth of 3 inches once each week to April 23, and from this date until the end of the experiment to the same depth daily.

Effluent of Filter No. 52 applied, 16½ gallons eighteen times a week, February 1 to May 1; 12½ gallons twenty-four times a week, May 2 to June 28; from June 29 to July 21, the amount of applied sewage varied from 3 gallons to 47½ gallons daily; 12½ gallons twelve times a week, July 22 to December 10. February 18, ½ inch of coke removed from surface of Filter No. 22 and thoroughly mixed with top foot of coke in Filter No. 58. April 15 to 21, experiment interrupted by freshet. Surface raked 3 inches deep once each week, April 1 to 22, and daily from April 23 to December 10.

*Summary of Filters 51 to 58 Inclusive.*

The following table gives the average analysis of the effluent of each filter for the entire period of operation : —

[Parts per 100,000.]

\* The filters marked with an asterisk belong to one series and those without a mark to the other. It will be observed that the series of which Filter No. 52 (coke) was the initial filter had effluents containing less organic matter and lower numbers of bacteria than the effluents of the series of which Filter No. 51 was the initial filter.

*Filter No. 59.*

This filter is one ten-thousandth of an acre in area, and contains, over the usual under-drains, 60 inches in depth of gravel stones of an effective size of 2.50 millimeters. Down through the middle of the filter an iron pipe 1 inch in diameter is passed, and the pipe reaches to within 6 inches of the bottom of the filter. The lower 6 inches of this pipe is perforated and to the top is attached an aspirator operated by the pressure of the city water supply. This filter was first put in operation April 1, 1895, and has received sewage at an average rate, up to Jan. 1, 1896, of 500,000 gallons per acre daily. The surface of the filter has been disturbed to a depth of 3 inches once each week and the applied sewage has uniformly disappeared immediately from the surface. From April 4 to September 2 the filter was aerated from 9 P.M. to 5 A.M. daily; from this date until November 1 the filter was not aerated; from November 1 until November 25 it was again aerated from 9 P.M. to 5 A.M.; from November 25 to December 7 there was no aëration, and from this last date to the end of the year it was again aerated from 9 P.M. to

5 A.M. When aëration was stopped in September the effluent of the filter contained 2.41 parts of nitrates in 100,000. The nitrates gradually became less and on October 30 were 1.35 parts in 100,000, and the quantity of albuminoid ammonia and oxygen consumed of the effluent had doubled. On November 12, twelve days after renewing aëration in the filter, the nitrates of the effluent had increased to 3.50 parts in 100,000 but the albuminoid ammonia and oxygen consumed of the effluent decreased very gradually. The second period of interruption of aëration did not affect the quality of the effluent. The following table gives the monthly averages of the analyses :—

Sewage applied, 54 gallons daily six days a week, April 1 to December 31. Sewage applied in the following manner: six doses of 5 gallons each applied in the forenoon and six doses of 4 gallons each in the afternoon. April 1, a piece of 1-inch pipe  $5\frac{1}{2}$  feet long, having holes bored in the lower 6 inches, was driven down through the center of filter; the lower end of the pipe is 6 inches above the bottom of the filter; a trap was attached to outlet. Filter aspirated eight hours each night, April 1 to September 1, November 1 to 24, December 7 to 31. April 10 to 21, experiment interrupted by freshet. April 21, 6 inches of gravel removed from filter, washed and replaced. Surface raked 3 inches deep once each week.

*Filter No. 60.*

This filter is one twenty-thousandth of an acre in area, and contains, over the usual under-drains, 60 inches in depth of sand of an effective size of 0.25 millimeter. To this filter has been applied, since September 8, the waste liquor resulting from cleansing rags in a paper mill by means of a boiling solution of caustic soda and lime. The rags cleaned are of all kinds and colors and the resulting liquor

is often very highly colored. It has been applied to the filter, at an average rate of 65,500 gallons per acre daily, without difficulty. The effluent of the filter, while greatly improved in appearance and analysis from the applied liquor, is still highly charged with organic matter in solution, and the degree of alkalinity of the liquor is apparently unfavorable to the development of the nitrifying organism in the filter.

*Average Analysis of Liquor applied to and Effluent from Filter No. 60.*

*Filter No. 61.*

This filter is one twenty-thousandth of an acre in area, and contains, over the usual under-drains, 60 inches in depth of sand of an effective size of 0.25 millimeter. To this filter has been applied the waste liquor from scouring wool at an average rate, since September 8, of 17,000 gallons per acre daily. The results thus far obtained have shown that, while this liquor can be filtered through sand and a large percentage of its organic matters removed, yet it is with such difficulty, owing to clogging and necessary removal of the surface layers of the sand of the filter, that a preliminary treatment to remove a large part of the dirt and fatty matters before filtration is essential.

*Filters Nos. VI. and VII.*

Filter No. VI. contained 60 inches in depth of sand of an effective size of 0.25 millimeter, and Filter No. VII. contained the same depth of coke breeze. To these two filters the effluent of Filter No. 61 was applied at an average rate, from October 1 to January 1, of 50,000 gallons per acre daily. Each filter disposed of the applied liquor readily, but it passed through the 5 feet of filtering material with little or no change, the organic matters present being of a very stable character and the degree of alkalinity obtained prejudicial to nitrification.

*Filter No. VIII.*

This filter contains 5 feet in depth of sand of an effective size of 0.25 millimeter, and has received the supernatant liquid resulting from precipitating the fat and dirt out of the strong waste wool scouring liquor by means of calcium chloride. This treatment with calcium chloride gives an almost complete clarification of the liquor, and its strength after treatment, estimated by albuminoid ammonia determinations, is about the same as the effluent of Filter No. 61. Filter No. VIII. has disposed of this clarified liquor readily at an average rate of 100,000 gallons per acre daily, but it has passed through the 5 feet of sand with very little change.

## FILTRATION OF WATER.

---

The investigations upon the purification of water by sand filtration have been continued throughout the year, and the data obtained by the results from the experimental filters at the station have been supplemented and strengthened by observations of the practical operation and the results obtained from the large filter (2.5 acres in area) of the water works of the city of Lawrence. All of the experimental filters in operation during 1894 were continued during 1895, and three new filters were constructed, containing sand of a character not before used, namely, Filter No. 62, containing 4 feet in depth of beach sand of an effective size of 0.40 millimeter; Filter No. 63, containing 2 feet in depth of "Berkshire" sand of an effective size of 0.16 millimeter, and Filter No. 64, containing 1 foot in depth of the "Berkshire" sand.

The general plan of the investigations was the same as in 1894 and the number of bacteria in the applied river water and in the effluent of each filter was determined daily. *B. prodigiosus* has been applied to all the filters in known quantities and at stated intervals, and the percentage removal of this germ by the several filters is considered to show the bacterial purification of the water, as the percentage removal of the ordinary water bacteria of the applied water shows the bacterial efficiency of the various filters, as explained in the last annual report.

The following table gives the average results obtained from the filtration of Merrimack River water during the year by the various filters:—

Summary of Average Daily Bacterial Results obtained from the Experimental Filtration of Merrimack River Water.

| NUMBER OF FILTER. | Date of Construction. | Effective Size of Sand. (Millimeter.) | Uniformity Coefficient. | Depth of Material. (Inches.) | Method of Operation. | Average Rate of Filtration. Gallons per Acre Daily. | AVERAGE NUMBER OF BACTERIA PER CUBIC CENTIMETER IN |           | Average Per Cent, which the Number of Bacteria in the Effluent was of the Number of Bacteria in Applied Water. | Average Bacterial Efficiency. |

† Reduced in depth to 36 inches August 1.

## DISCUSSION OF BACTERIAL EFFICIENCY OF THE FILTERS.

We see by this table that the average bacterial efficiency of the filters during 1895 has (excluding the results obtained from Filter No. 42, which has contained for a portion of its period of operation only 1 inch in depth of sand) varied from 97.69 per cent. on the part of Filter No. 63 to 99.75 per cent. on the part of Filter No. 41. Filter No. 63 was, in common with filters No. 62 and 64, a new filter, having been operated only three months at the time the averages were made, and containing but 2 feet in depth of sand. Excluding from the averages of the year filters Nos. 42, 62, 63 and 64, for the reasons given, the bacterial efficiency of the remaining filters — filters which had been in operation for a period during 1894 and earlier years — varies from 98.74 per cent. on the part of Filter No. 45 to 99.75 per cent. on the part of Filter No. 41. All the filters, with the exception of filters Nos. 3 B, 7 A and 8 A, are  $\frac{1}{20}$  of an acre in area and within the buildings. These small filters cannot be operated during the winter months on account of complications from freezing, which causes the formation of channels between the body of the sand and the sides of the iron tanks, and on account of the evolution of air from the saturated water within the filters. These facts have been thoroughly explained in previous reports, and it is enough at this time to state that they are simply effects of the location of these small experimental filters and not factors in filtration. Filters Nos. 3 B, 7 A and 8 A are located out of doors and are each  $\frac{1}{20}$  of an acre in area. Filter No. 3 B is an intermittent filter and Filter No. 8 A is a continuous filter, and both have been operated constantly since their construction, Sept. 23, 1893; and, although they are not protected from the weather, as filters in this climate undoubtedly should be, the results from them are probably the most important obtained at the experiment station, and illustrate more completely than the results of operation of the other filters the average yearly bacterial efficiency that can be obtained by filters containing 5 feet in depth of medium sand and operating at normal rates.

The average daily number of bacteria per cubic centimeter in the effluent of Filter No. 3 B for the year is shown by the table on page 532, and a similar table on page 538 gives the same information in regard to the effluent of Filter No. 8 A. In studying these results month by month we learn in the case of Filter No. 3 B (intermittent)

the following facts: the average bacterial efficiency of the year was 99.16 per cent., but on several occasions during the winter months the bacterial efficiency was low. On January 8 the surface of the filter was raked to the depth of 1 inch to remove clogging, and the filter was subsequently put in operation by filling from above with canal water, and on January 9 and 10 the bacterial efficiency of the filter was 91.70 and 96.50 per cent. respectively, but on no other day of the month was its efficiency less than 98 per cent. From February 6 until February 12, inclusive, owing to a frozen feed-pipe, the filter stood uncovered with water and became frozen to a considerable depth. The bacterial results of the next few days were of course poor, and should hardly be included in the yearly averages. During the winter months, up to March 11, the filter had been operated at a rate of 1,500,000 gallons per acre daily, but on this date, owing to an increased supply of water, the rate was increased to 5,000,000 gallons per acre daily, and this rate continued until November 24. For the six days following this increase of rate the bacterial efficiency averaged 94.85 per cent., but from this time throughout the remainder of the year the daily bacterial efficiency was never less than 98 per cent., and for months at a time was 99.50 per cent. or more. The comparatively low bacterial efficiency obtained at times during the winter months was largely due to the exposure of the surface of the sand to extremely cold weather, and could be avoided to a large extent with covered filters.

Studying the bacterial results of Filter No. 8 A (continuous), given in the table on page 538, we find that its daily bacterial efficiency for the year was 99.73 per cent. Throughout January and February and the first eleven days of March this filter, although exposed to the weather, gave a bacterial efficiency that was on no occasion less than 99.35 per cent. During this period the filter was operating at a rate of 1,500,000 gallons per acre daily. On March 11, owing to an increased water supply, the rate of filtration was increased to 5,000,000 gallons per acre daily, and this rate continued until November 25. For a period of eight days following this increase of rate, that is, from March 12 to 19 inclusive, the bacterial efficiency of the filter averaged 96.30 per cent., with a minimum efficiency of 92.30 per cent. From this last date until the close of the year the bacterial efficiency of the filter was never less than 98 per cent., and only on two or three occasions less than 99 per cent., and for months at a time maintained a uniform efficiency of 99.50 per cent. or more.

The bacterial results obtained from these large filters upon October 3 and 4 are significant when compared with the results obtained on these days from the small filters. On these two days the number of bacteria in the applied water was 319,000 and 110,000 per cubic centimeter, respectively, and in Filter No. 3 B, 233 and 90, Filter No. 7 A, 24 and 55, and Filter No. 8 A, 22 and 7 per cubic centimeter, respectively. The effluents of the small filters all contained a much larger number of bacteria per cubic centimeter upon these days.

*Bacterial Efficiency of the Small In-door Filters.*

These filters, as has been stated, can be operated only a portion of the year, and have been largely used during 1894 and 1895 in studying the bacterial results obtained from filters of different depths, material and period of operation when they are subjected to fluctuations of rate of filtration, deep scrapings, raking, etc., and have consequently been operated in many instances in a manner known to be unfavorable to the greatest average bacterial efficiency. In the tables given in a subsequent portion of this report and showing the daily bacterial efficiency of filters No. 18 to 64, inclusive, the bacterial results of those days when the filters were subjected to abnormal treatments are of samples taken before such treatment.

The average daily bacterial results of the following day were, however, necessarily affected in many instances. For this reason the results are not considered to be as representative as the results from filters Nos. 3 B and 8 A. Another complication entering into the summarizing of the results of these small filters is the fact that, in the middle of their period of operation during 1895, those containing approximately 5 feet in depth of sand were cut down to a depth of 3 feet. All of these filters, that contained at the beginning of their period of operation in 1895, 5 feet in depth of filtering material, gave a bacterial efficiency varying from 98.74 per cent. to 99.75 per cent., operating at rates of filtration varying from 2,000,000 to 7,000,000 gallons per acre daily. Filter No. 38, containing approximately 20 inches in depth of sand, and operating at an average rate of 940,000 gallons per acre daily, had a bacterial efficiency of 99.50 per cent., and Filter No. 46, containing approximately 12 inches in depth of sand, and operating at the rate of 4,480,000 gallons per acre daily, had a bacterial efficiency of 98.95 per cent.

In calculating the bacterial efficiency of these small filters the results obtained during the first ten days of their operation, or period of biological construction, are omitted.

*Bacterial Purification.*

The chief object of water filtration is the removal of disease germs. The results of filtration for the year, given in the preceding table and discussion, are entirely confined to the removal of the bacteria normally present in the Merrimack River water as it flows past Lawrence, after receiving the sewage of Lowell, Manchester, Concord and many other cities and towns upon its water-shed. These bacteria are of many kinds, and are chiefly those found in the wastes of human and animal life together with many whose natural habitat is the river water. To strengthen and confirm the results obtained by sand filtration of this water, it has been the custom for the past few years at the station to add at times to the water applied to the filters a pure culture of *B. prodigiosus*. The reasons for the application of this germ are that it is apparently incapable of growth within the filters and their under-drains, can be readily detected if present in the effluents, and hence its percentage removal by the filters more definitely determined than the percentage removal of the various kinds of bacteria normally present in the applied water. Some of these bacteria, we have been led to believe by results obtained in former years, are capable of multiplying within the filters, and in this manner preventing the number of bacteria present in the effluent representing the number which have passed through the entire filter. The tables showing the number of *B. prodigiosus* in the applied water and in the effluents of the various filters are given on page 529 and following pages. In studying these tables we see that the bacterial purification obtained by the various filters has been much greater than their bacterial efficiency. The bacterial purification results obtained from filters Nos. 3 B and 8 A may be summarized as follows: the rate of filtration of Filter No. 3 B was increased March 11 from 1,500,000 gallons to 5,000,000 gallons per acre daily, and on this day *B. prodigiosus* was first applied. Each cubic centimeter of applied canal water upon this day contained 617, and on the five following days 500, 970, 1,882, 870 and 244 germs of *B. prodigiosus*, respectively, and each cubic centimeter of the effluent contained on these days 5, 10, 5, 5, 2 and 1, respectively, showing an average bacterial purification for these days of 94.50 per cent. The application of *B. prodigiosus* was continued at the same rate until April 10, but only once after March 16 was its presence detected in the effluent. Such a great fluctuation of rate as that given

above, and which resulted in low bacterial efficiency and purification, is not a necessary occurrence in natural sand filtration, and the results obtained must be regarded as abnormal.

From September 2 to November 21, when the filter was operating normally at a 5,000,000 gallon rate, *B. prodigiosus* was again applied in the same proportion for ten hours daily and on only five days was its presence detected in the effluent. The bacterial purification obtained by the filter during these three months was 99.99+ per cent. This same germ was applied in the same proportion to Filter No. 8 A from March 11 to April 10, and the rate of operation of this filter was increased to the same extent on March 12 as that of Filter No. 3 B. It is of interest to note that on March 11 this germ did not appear in the effluent, but that on March 12, the day on which the rate was increased 70 per cent., the effluent contained 41 per cubic centimeter, and its presence was noted upon fifteen of the days upon which it was applied up to April 10. The average bacterial purification of the filter during the first six days of its application was 87.9 per cent. and for the remaining period up to April 10 was 99.85 per cent.

From May 6 to November 19, and from this last date until December 1, during which entire period the filter was running normally at a rate of 5,000,000 gallons per acre daily, *B. prodigiosus* was applied up to November 19 in the same proportion as during the period from March 11 to April 10, and from November 19 to December 1 in numbers twice as great, and on only five days in this entire period was its presence detected in the effluent of this filter, giving a bacterial purification of 99.99+ per cent.

Filter No. 7 A of the same area as filters Nos. 3 B and 8 A, but containing only 2 feet in depth of a somewhat coarser sand, had *B. prodigiosus* applied to it in the same proportion as to filters Nos. 3 B and 8 A ten hours daily, from August 20 to November 19 inclusive, during which period the filter was filtering at a rate of 5,000,000 gallons per acre daily, and the presence of the germ was detected in the effluent upon sixteen days. Of these sixteen days twelve were of the first three or four days following scraping to remove clogging of the surface of the filter.

The bacterial purification obtained by the small in-door filters has been uniformly greater than their bacterial efficiency.

*Increased Effectiveness of Filters due to Age or Length of Period of Service.*

Bacterial results have been given from time to time tending to show that the bacterial efficiency of sand filters increased in proportion to their period of service. This tendency towards increased effectiveness with increased age is made more clear by the results obtained during the past year (1895) from those filters which have been in operation at the station for several years. This increased efficiency of the filters is probably due to the accumulation of organic and mineral matter of a gelatinous character upon the sand grains of the filter, together with an increased compactness of the sand caused by a moderate amount of settling. Filter No. 18 A, the oldest filter in use at the station during 1895, and one of the two filters with greatest effective size of sand grain, was in operation during 1893 at an average rate of about 2,000,000 gallons per acre daily, and its bacterial efficiency was 96.75 per cent. During 1894 its rate of operation was 4,500,000 gallons per acre daily and its efficiency was 98.97 per cent., and during 1895 it has been operating approximately at the same rate as during 1894, and its bacterial efficiency has been 99.57 per cent. This increased bacterial efficiency caused by length of period of service is considerably more marked with filters constructed of medium coarse or coarse sands than it is with those constructed of medium fine sand. The following table of results from filters, all of which were constructed during 1893, is interesting as bearing upon this point. All of these filters contained during 1893 and 1894 5 feet in depth of sand, but Aug. 1, 1895, filters Nos. 43, 44, 45 and 46 were reduced in depth to 3 feet.

*Table showing the Bacterial Efficiency of Filters during Successive Years of their Period of Service.*

*Effect of Different Depths of Filtering Material upon Bacterial Efficiency.*

If filters 2 or 3 feet in depth can by careful supervision produce as uniformly satisfactory results from a hygienic point of view as filters containing 5 feet in depth of filtering material, their cost of construction would be materially lessened. The results attained at the station have indicated that nearly as satisfactory results are given by shallow filters as by deeper ones, especially after a period of service of some considerable length, but that they are much more sensitive to disturbing influences. This really means that if a filter in practical operation is to be supervised by experts, satisfactory and safe results can be secured with a shallow depth of sand, but that if its operation is to be entrusted to unskilled hands, not fully acquainted with the essential features of successful sand filtration, the steadying influence of a considerable depth of sand is all important. This is especially so in winter, when formation of ice and freezing of the surface sand is liable to occur, as at such times the best and most skilful handling would be necessary, with a shallow filter, to produce satisfactory results. The depth of sand in the Lawrence city filter and the method of under-draining, by which the rapidity of filtration is checked, have undoubtedly been of extreme value in producing good hygienic results.

To make a really just comparison between filters of different depths of filtering material, the filters should be of the same grade of sand, of the same period of service and should have been operated at the same rate. We can make no such absolute comparison of any of the filters in operation during 1895, but a comparison of some value can be shown by the following table of results of the three days preceding and three days following scraping the surfaces of filters Nos. 7 A and 8 A. It can also be stated that scraping the surface of Filter No. 8 A did not affect the bacterial purification results obtained, while scraping the surface of Filter No. 7 A almost invariably caused the appearance of *B. prodigiosus* in the effluent for the three or four days following.

The second table shows the number of bacteria in the effluents of these two filters at periods between scraping, when the filters were operating at approximately the same rate, namely, 5,000,000 gallons per acre daily.

On August 1, filters Nos. 43, 44, 45 and 47, which contained, when first constructed in 1893, 5 feet in depth of sand, but which had grown gradually shallower by the removal of sand at times of scraping, were cut down to the extent necessary to cause them to contain 3 feet in depth of sand over their under-drains. On August 31, filters Nos. 18 A and 50 were treated in a like manner. To reduce them to the required depth it was necessary to remove a foot or more of sand.

The purpose of this reduction in depth was to study and compare the results obtained from the same filters when of different depths, but this purpose was defeated to some extent by the fact that in removing so great a depth of filtering material, which had been rendered doubly effective by the organic matter accumulated within it, we were practically establishing new filters. The results obtained from them therefore could not in fairness be compared with the results just previously obtained, when the filters were of greater depth; neither could they be compared with results obtained during the first few months of operation of these filters, as at that time there was practically no organic matter or gelatinous films upon the sand grains, while of course on the sand remaining in the filters after their reduction in depth these gelatinous films were present to a considerable extent. It can be said, however, that these filters, after a period of biological construction, gave nearly as great bacterial efficiency under normal conditions of filtration, but were more sensitive to disturbing influences. A fairer comparison can be made between filters Nos. 46 and 47. Filter No. 46, containing approximately 12 inches in depth of sand of an effective size of 0.29 millimeter, had a bacterial efficiency for the year of 98.95 per cent., with an average rate of filtration of 4,480,000 gallons per acre daily, while Filter No. 47, containing approximately 60 inches in depth of sand of the same grade up to August 1, and after this date 36 inches in depth of sand, had a bacterial efficiency for the year of 99.38 per cent., with an average rate of filtration of 6,600,000 gallons per acre daily. From May 1 to August 1 Filter No. 46 was scraped ten times to remove clogging; the depth of sand removed at each scraping averaged 0.41 of an inch, and the average number of bacteria per cubic centimeter in the effluent for the twenty-four hours following these scrapings was 209. Filter No. 47 was scraped thirteen times to remove clogging between May 1 and August 1; the depth of sand removed each time averaged 0.33 of an inch, and the average number of bacteria in

each cubic centimeter of the effluent for the twenty-four hours following scraping averaged 86. These two filters are of the same age.

*The Effect of the Amount of Loss of Head upon Bacterial Efficiency.*

It has been stated in the last two reports that, contrary to some European experience, the experimental filters at Lawrence under ordinary conditions show no diminution in the removal of bacteria when the loss of head, or measurement of the frictional resistance of the sand of the filter to the passage of water, reaches nearly or quite the total depth of the filter (sand and water). The results obtained for 1895 from filters operating under normal conditions emphatically confirm the earlier ones. In studying the bacterial efficiency of the various filters when their loss of head was at or approaching its maximum, occasional results can be found giving slightly higher numbers of bacteria, but generally not enough higher to lower the bacterial efficiency of the filter more than a small fraction of one per cent. If we take the results obtained from filters Nos. 3 B, 7 A and 8 A to represent the results obtained by filters operating under normal conditions, we learn the following facts regarding this point: Filter No. 3 B was scraped ten times during 1895 to remove clogging and keep the rate to the prescribed limit; that is to say, the loss of head reached its maximum ten times, but the lowest bacterial efficiency obtained at any time upon the day immediately preceding scraping was 99.25 per cent. Filter No. 8 A was scraped sixteen times during the year, and the lowest bacterial efficiency obtained at any time upon the day immediately preceding scraping was 99.22 per cent. Filter No. 7 A contains but 2 feet in depth of sand and was scraped twelve times during its period of operation in 1895, and its lowest bacterial efficiency upon any day immediately preceding scraping was 98.90 per cent.

*Effect of Fluctuation in Rate upon Bacterial Efficiency.*

Under the discussion of the bacterial efficiency obtained during the year by filters Nos. 3 B and 8 A on page 506, the poor results obtained for a few days in March, following the increase of rate of each filter from 1,500,000 to 5,000,000 gallons per acre daily, has been noted. At the time when these increments of rate were made the filters had been scraped to a depth of 1 inch and then raked to a depth of 1 inch. This was a combination of factors well calcu-

lated to produce low efficiency and not necessary in actual filtration. It has been shown by the table on page 513 that scraping Filter No. 8 A had little if any effect upon its bacterial efficiency, and many thousand samples of the effluents of intermittent filters, taken after flooding and when the rates of filtration of the filters were slowly increasing to the maximum, prove that rates may be greatly increased without diminishing bacterial efficiency.

Violent fluctuations of rate, either above or below the normal, produce mechanical disturbances of the filtering materials and diminished bacterial efficiency for periods more or less prolonged.

The following table records some results obtained by fluctuating the rates of filtration. The number of bacteria per cubic centimeter in the effluents before the changes were made are given, together with the maximum number found after the change. Each set of results represents from ten to twenty bacterial analyses of samples of the effluent, most of which were collected at about the time when the water, which was in the upper portion of the filter when the rate was changed, was flowing from the filter.

*Summary of Bacterial Results to show the Effect of Fluctuating the Rate of Filtration.*
